

A Few Tools to Help Manage Your Data

Managing data can be laborious and demanding. But the task is critical in the age of AI. Help is available in the form of data management tools that are both open source and proprietary.

Data management is the process of gathering, arranging, safeguarding and preserving an organisation's data so that it may be examined for business choices. It helps simplify and shorten the time required for critical tasks. For instance, to prepare raw data for analysis, it must be cleaned, formatted and corrected.

It may also involve merging different datasets like .csv, .tsv, and .xlsx. These could be structured, semi-structured or unstructured.

ETL and ELT

The automated flow of data between systems is made possible by data pipelines. The purpose of ETL (extract,

transform, load) is to load data into an organisation's data warehouse after transforming it from one system. ELT (extract, load and transform) performs data transformations directly within the data warehouse. Unlike ETL, ELT allows raw data to be sent directly to the data warehouse, eliminating the need for staging processes.
