

Azure Ink Recognizer

The Azure platform provides loads of cognitive and AI/ML services for text recognition, extraction and verification including Form Recognizer, Cognitive Services and OCR (optical character recognition) APIs. However, the Azure Ink Recognizer Service is unique in that it can recognise digital written text such as signatures in banks, and can scan documents and medical reports.

Figure 1: Ink Recognizer API usage

services API account and called using the REST API request in C#, Java, or JavaScript code using JSON request. The response is a JSON string with the tag 'recognizedString'.

Typically, it is also based on pattern matching, which is similar to OCR. However, OCR is based on scanned digital images of manually written text in ink or print, whereas Ink Recognizer recognises text that is written digitally and is helpful in validating, for example, signatures in immigration or visa documents, in licences and bank documents, etc.

Ink Recognizer can recognise handwritten text in 63 languages (locales), and can be used for recognising geometric shapes such as a rectangle or circle or a combination of both. It is part of the cognitive

Azure Machine Learning services

If you are looking for a cloud-based service that can help you build, train, and deploy machine learning models using various tools and frameworks, you may want to check out Azure Machine Learning. This flexible and powerful platform lets you do the following:

- Create and manage machine learning experiments and track their results and metrics.
- Use automated machine learning to find the best model for your data and scenario without writing code.
- Use Azure Machine Learning Designer to create machine learning pipelines using a drag-and-drop interface.
- Use Azure Machine Learning Studio to access a web-based IDE for coding, debugging, and testing machine learning models.
- Use Azure Machine Learning notebooks to write and run Python code in Jupyter notebooks hosted on the cloud.
- Use Azure Machine Learning SDKs to programmatically interact with Azure Machine Learning services from Python, R, or .NET.
- Use Azure Machine Learning MLOps to implement DevOps practices for machine learning, such as version control, testing, deployment, and monitoring.

Azure Cognitive Search

Azure Cognitive Search is a search-as-a-service solution that enables the addition of sophisticated search capabilities to applications. It integrates AI capabilities to enrich and index content.

Technical insights

- Full-text search, indexing, and querying capabilities.
- Built-in cognitive skills like language detection, entity recognition, and key phrase extraction.
- Has REST API and SDKs for easy integration.
- Scalable and fully managed search service.

Azure Form Recognizer

Azure Form Recognizer automates the extraction of text, key-value pairs, and tables from documents. It is particularly useful for processing forms and invoices.

Technical insights

- Uses machine learning models to understand and extract information.
- Supports pre-built models for invoices, receipts, and business cards.
- Has customisable models for specific document types.
- Provides REST APIs for integration.
