

Google releases alpha version of Genkit for Go

Google has announced the alpha release of Genkit for Go, an open source framework aimed at empowering Go developers, or ‘gophers’, to build AI applications and cloud services.

Developed in collaboration between the Firebase and Go teams, Genkit for Go seeks to combine Go’s simplicity, scalability, and security with the robust libraries and tools offered by Genkit. The framework is designed to streamline the development of sophisticated AI applications, such as intelligent assistants, customer support agents, and data transformation tools.

The intuitive libraries of Genkit for Go are written in pure Go, and follow idiomatic Go conventions, ensuring easy integration into existing projects. *Dotprompt* is a file format for prompt engineering that allows developers to define templates, schemas, and model configurations within a single *.prompt* file.

Genkit includes plugins for various AI services and databases, such as Google AI, Vertex AI, Ollama, and Pinecone. The framework is extensible, encouraging community contributions.

The framework integrates with Google Cloud’s operations suite and supports OpenTelemetry, providing robust monitoring for AI applications in production environments.

As Genkit for Go is currently in its alpha stage, it’s ideal for experimentation and prototyping. Google invites developers to explore the framework and provide feedback to help shape its future.

For those interested, the project’s GitHub page offers *Getting Started* guides, documentation, and community resources. Google has also created a Discord server for direct communication with the Genkit team and other developers.

Genkit for Go represents a significant step towards making advanced AI capabilities more accessible to the Go community.

Although SDCI has been mentioned in AMD programmer documentation since last year, the Linux kernel patches are just now emerging, building on the recent PCIe TPH developments. AMD’s SDCI enables DMA data to be pre-fetched into the cache of target CCXs rather than being routed first to DRAM. This process is designed to reduce latency, enhance performance, and conserve memory bandwidth.

KDE Frameworks 6.5 released

The KDE Project has announced the release of KDE Frameworks 6.5, the latest update to its extensive collection of over 70 add-on libraries for Qt, which provide essential functionality for the Plasma desktop environment and various KDE applications.

KDE Frameworks 6.5 introduces several enhancements, including improved accessibility for multiple controls on the *Shortcuts* page within *System Settings* and standardising the red X icon used for “remove this abstract thing,” as recommended by the Human Interface Guidelines (HIG) in the Breeze icon theme. Additionally, the update enhances support for applications running on the Plasma Wayland session.

This release also brings new tooltips to the open/save dialogs and other areas in Dolphin’s Places panel, displaying relevant information when hovered. Performance improvements have been made for components across KDE that utilise the `KFileItem::isHidden` element. The “Get New [thing]” dialogs have also been upgraded to allow file downloads directly from the details page of an entry containing multiple items.

KDE Frameworks 6.5 enhances support for applications that separate their transient state data from persistent configuration data by storing the state config file in the standard XDG state folder under `~/.local/state/`. It also adds functionality for apps to remember their window size, maximisation state, and position in the Plasma X11 session.

Security has been bolstered in this release, with KAuth now using file descriptors instead of file paths, along with corresponding support on the *Login Screen* page in *System Settings*. The update also refines the “Click in track to scroll by one page at a time” feature and improves support for immutable distributions like Fedora Kinoite.

Several bugs have been fixed in KDE Frameworks 6.5, including a Plasma crash that occurred when attempting to reassign a shortcut already in use by another widget. The full changelog provides further details on the changes in this release.

KDE Frameworks 6.5 will soon be available in the stable repositories of popular rolling-release distributions such as KDE neon, Arch Linux, and openSUSE Tumbleweed, as well as in other well-known distributions like Fedora Linux.
