

Test Your Software with JMeter

Software applications have to undergo various tests to ensure quality. One such test is load testing, which helps to determine how the application behaves when multiple users or requests hit it simultaneously. Apache JMeter (JMeter) is one of the best open source tools for this job.

JMeter is an open source desktop based application for testing software. It is a pure Java application used for analysing and measuring the performance of software through a variety of graphical reports. We can perform load testing, stress testing and functional testing for applications with JMeter.

If there are any flaws in the application such as buffer overflow or memory leaks, JMeter can easily simulate the situation in your own environment and avoid production issue surprises. It can help achieve all this easily, even if you have minimum or no knowledge in coding.

Installation of JMeter

Detailed installation steps for Windows and Linux are given at <https://jmeter.apache.org/usermanual/get-started.html>, and for Mac at <https://psychowhiz.medium.com/install-jmeter-on-mac-25531bc2b2ad>.

The following are some of the types of applications that can be tested with this tool:

- Websites: HTTPS and HTTP
- Web services: REST, SOAP and GraphQL
- Database servers
- FTP servers

- LDAP servers
- Mail servers: SMTP, POP3, IMAP
- TCP servers

Elements of JMeter

There are different elements in JMeter, each performing a task to achieve a goal. A few elements that are important
