

How to do Reverse Tunnelling with the Amazon EC2 Instance

This article describes how to share a local running website (services) in your system with the external world and map it with a domain. You can use your local system as a Web server without static IP, using reverse tunnelling.

Reverse tunnelling is a method of tunnelling from a mobile host (cloud server) to a home agent (local system), which makes it possible for everyone to communicate via the network. For example, `http://<IP>:9033` will access the website running on your laptop without static IP by using an EC2 instance configured as a reverse tunnelling server.
