

Anypoint Platform, technology partners help customers achieve greater speed, agility, and efficiency by creating reusable building blocks, including connectors, APIs, and templates, that can accelerate the pace of innovation, said the company.

PostHog raises US\$ 15 million in fresh funding

PostHog has announced that it has raised US\$ 15 million in a fresh round of funding and has introduced major new free features for users of data warehouses. The company's series B funding was led by existing investor Y Combinator's Continuity Fund, with participation from GV (formerly Google Ventures), and takes PostHog's total funding to over US\$ 27 million, despite the company only

recently turning one-year old. As part of the round, Ali Rowghani, managing partner at YC Continuity, and former COO at Twitter and CFO at Pixar, will join the PostHog board.

PostHog will use the funding to focus on another major input, with the best people

in the world joining the team. This will accelerate improvements to self-hosted deployment at scale, data warehouse integration and tutorials, user experience, marketing, and customer success.

James Hawkins, co-founder and CEO, said, "To-date, product analytics for those using data warehouses has been painful — developers are between a rock and a hard place. They can either code their own data export libraries and their own SQL, or they'd have to send user data to a third party and incur massive data transfer charges. Companies want to leverage their data more than ever before, data warehouses are getting cheaper and simpler, and we can support their adoption as they become mainstream. PostHog means data analysts no longer need to lose hours producing simple product usage visualisations."

The company said that PostHog's mission is to increase the number of successful products in the world. Its open source platform lets developers track product usage, understand the impact of new features on user behaviour, and integrate product and user data with data warehouses – all without sending any data to a third party.

CloudLinux makes open source UChecker available for free

CloudLinux has announced that it is making open source software UChecker available for free. This software scans Linux servers for vulnerable libraries that are outdated and being used by other applications. It provides detailed actionable information regarding which application is using which vulnerable library and needs to be updated, which helps improve the security awareness patching process.

Jim Jackson, president and chief revenue officer, CloudLinux, said, "Patch management is a challenging area of security and IT operations because so many different systems require patching, plus they have to be tested before being deployed. Also, some patches require reconfigurations and reboots of servers that are difficult to take offline for very long. Time is critical because hackers look to exploit vulnerabilities, so it's always a race for IT teams to apply security patches."

UChecker detects and reports those shared libraries that are not up-to-date, both on disk and in memory. Short for 'username checker', it can be integrated with tools like Nagios or other monitoring and management tools to alert about systems running outdated libraries. UChecker works with all modern Linux distributions under the GNU General Public License.

Jahia Solutions Group announces new release of jExperience

Jahia Solutions Group has announced a new release of jExperience, powered by Apache Unomi, the open source customer data platform (CDP) that allows businesses to collect and analyse first-party customer data, segment audiences, and personalise content – all on the existing content management system (CMS).

Serge Huber, chief technology officer at Jahia, said, "With the evolution of consumer behaviour, understanding how to successfully bridge the gap between customer data, digital experiences and personalisation has become increasingly critical for business success, and to properly collect and use first-party customer data. jExperience has been designed to transform your CMS into a DXP that simplifies customer data collection and management, delivering the personalised digital experiences that today's customers expect."

Jahia takes the complexity out of customer data collection and management by linking disparate data silos together from across all sales and marketing tools. Jahia users gain insights into customer behaviour to create and deploy repeatable segmentation and personalisation strategies to drive more tailored experiences, build valuable and synchronised journeys, and drive conversion rates.

Apache Unomi, the open source CDP and data foundation of jExperience, was developed in-house at Jahia and then donated to the Apache Software Foundation. jExperience adds enterprise personalisation capabilities so users can easily act on customer data.
