

Using MongoDB *with* R Programming

MongoDB is a popular open source document database known for its performance and scalability. It contains a database model that manages the abundant data in any enterprise application. The R programming language has several packages that deal with MongoDB effectively, to extract and manipulate the data.

Eliot Horowitz and Dwight Merriman developed MongoDB in 2007 to address the issue of scalability of data. In 2009, it was made an open source project and people started using it because of its amazing features.

The many prominent features of MongoDB include the following.

- **High performance:** It supports embedded documents; so I/O operations are fewer. It also handles indexes; so there's faster query response in comparison to relational database systems.
- **Excellent features for Query:** It supports all CRUD operations of querying efficiently. It also comprises text search features and aggregation features.
- **High availability:** It provides the great functionality of auto replication; so availability is high.
- **Horizontal scalability:** It provides the sharding feature to handle horizontal scalability.
