

Ampere teams up with Oregon State University's Open Source Lab

Ampere has donated its first-generation Ampere eMAG server processors to Oregon State University's (OSU) Open Source Lab. This will allow members of the community to develop and test open source projects on the Arm AArch64 architecture platform.

Mauri Whalen, vice president of software engineering at Ampere said, "Ampere is committed to providing access to an open environment to expand the ecosystem and optimise the developer experience for next-generation cloud applications. We look forward to working with OSU's Open Source Lab and the OpenStack community to expand the development resources to enable open innovation."

The Open Source Lab is a non-profit organisation working for the advancement of open source technologies. The lab aims to accelerate the growth of high-impact open source software projects and promote a culture of accessibility and increased productivity. It plans to do so by enabling innovative projects and distributing software to millions of users globally.

Lance Albertson, director of Oregon State University, Open Source Lab, said, "The OSU Open Source Lab has partnered with Ampere to provide free access to the AARCH64 platform for FOSS projects. We have built an OpenStack cluster using Ampere Computing eMAG AARCH64 servers to provide flexible access using virtual machines for projects. Besides being impressed with the performance and ease of use, we've been very happy with the lower power consumption of the eMAG servers. In a rack that includes 12 eMAG HR350A servers, two 10g Arista switches, and one ToR HP switch, the 12 servers only use around 60 per cent of the total power in the rack with the rest being used by the three switches."

NetApp completes acquisition of Spot

NetApp has announced that it has completed its acquisition of cloud services company Spot. Spot by NetApp will deliver application-driven infrastructures (ADIs), cloud infrastructures that use analytics, and machine learning to continuously adapt to the needs of applications.

Cyral launches Project Approzium

Cyral has launched Approzium, an open source security project that has been designed to directly empower developers to improve monitoring and tracing of database services in the cloud or on-premises. Approzium is designed to work standalone and does not require the use of Cyral's commercial platform.

Manav Mittal, CEO of Cyral, said, "This unique data layer security project could only be successful if it's open source since it's going to be integrated into application code. By open sourcing the code, we wanted to eliminate any concern engineers would have about putting a third party component in their application."

Approzium security and performance metrics are by default sent to a Grafana dashboard. The company said that minor code changes make it easy to run a Datadog agent so that the metrics may be sent to a Datadog dashboard or whatever tool the development team prefers to use.

Cyral had launched the open source brewOPA project in February this year. This move was aimed to make it easier for developers, DevOps, and SecOps teams to interface with policy engines of the future.
