

Figure 1: Azure blockchain supply chain architecture

- Connects various data producers and consumers to or from the blockchain
- Integrates legacy tools, systems and protocols
- Dives into end-to-end examples, or solutions to common patterns
- Integrates traditional DevOps practices into a distributed application environment

Azure blockchain development kit for Ethereum helps developers create and deploy Ethereum based apps on Azure Blockchain Service or the Ethereum blockchain. The Ethereum development kit comes as an extension to Microsoft's source code editor Visual Studio Code, allowing developers to create and deploy Ethereum smart contracts and utilise open source blockchain tools such as Solidity and Truffle.

Azure Blockchain Workbench

Similar to the AWS blockchain template, which provides pre-built

templates to be used for cloud based blockchain platforms to build Ethereum or Hyperledger Fabric blockchain environments, Azure also provides a facility called Azure Blockchain Workbench which can simplify a developer's life by providing pre-built infrastructure, as well as network and security services to accelerate the development of a blockchain platform.

Azure Blockchain Workbench is a three-stacked service, as shown in Figure 3. Here, SaaS adapters like SAP or Office365 integrate with other Azure services for data management, security services and management activities, and the underlying platform services from blockchain platforms like Ethereum, Corda, Quorum and Hyperledger Fabric.

This stacked service provides users the facility to dynamically pick, choose and tailor the services as needed on targeted architecture, and use the flexibility to integrate with

any Azure native services required for the solution (like security or monitoring services).

Quorum on Azure Blockchain Service

Azure Blockchain Service is an integrated one-point service to support multiple blockchain platforms like Ethereum, Hyperledger Fabric, Corda, Chaincode and Quorum. It is currently in preview to provide support for Ethereum Quorum Ledger using the Istanbul Byzantine Fault Tolerance (IBFT) protocol. The actual purpose of Azure Blockchain Service is to provide support for multiple ledger protocols to be released in the future.

You can use Azure Blockchain Service to create a blockchain application like asset transfer or contract management, and to manipulate the code using Scala, Python or Java to create smart contracts. Azure Blockchain Service can be created with any protocol, like
