

Figure 2: Blockchain workflow architecture

Quorum or Ethereum. For this you need to create a blockchain consortium member, and it requires various attributes as listed below.

Azure subscription: You need to use an Azure subscription like an enterprise or organisation connected directory.

Resource group: You first need to create a resource group to tag your blockchain platform services together to a particular role and access permission.

Region: Since Azure Blockchain Platform Service is in preview, there is a limited region that supports this service. Hence, choosing the right region that is suitable for your deployment architecture is very important during the initial setup.

Protocol: This is the stage where you select the right protocol, as Azure Blockchain Service supports Quorum, Ethereum, Corda, Chain or Hyperledger Fabric protocols. Each works on its own consensus algorithm. Hence, this is a very important stage

Figure 3: Azure Blockchain Workbench services

where you need to identify the right choice of protocol based on the use case, community member size, number of nodes in the platform, and the level of security to be used.

Consortium: Finally, you prepare the consortium for blockchain service, which decides the mechanism of node management like voting and multi-node approval, to name a few.

Member: This is the stage where you create a unique member name for the service that you are creating, using a selected protocol like Quorum protocol and consortium in order to deploy the same.

Member protection: This is one of the peripheral activities where you protect the member with a password, using key vault or AD protection.
