at the technical debt acquired by an ML system? Traditionally, we have OOPS concepts like abstraction and encapsulation. But ML systems often, by their very nature, violate those boundaries based on various traits and prejudices. So, how does one measure the technical debt of an ML system? The paper discusses some of the

relevant questions that are given below.

1. How easily can a new approach (design, algorithm and model) be retrofitted and tested?
2. How entangled are the data dependencies? For example, if I want to get rid of some input data stream, what all do I need to modify?
3. Can we measure the impact of a

new change precisely?

4. How are the models integrated? Does a change in one cause others to degrade?
5. If a new person joins the team, how quickly can she/he adopt?
