

Figure 10: Inspecting the container environment

Figure 11: Viewing a container's computing resources usage statistics

Remember the image we saved as a tar file for migrating it from Docker Toolbox to Docker Desktop? It is now time to load that image. Run the following command to do so:

```
$docker load --input <image_name>.tar
```

Today, Docker has become an integral part of all DevOps (including DevSecOps, GitOps, AIOps, MLOps, etc) pipelines. It makes developing, building, and shipping containerised applications very easy. By using Docker containers, developers have to worry less about

project dependencies as well as differences between development and deployment environments. Docker for Windows is another step towards this, as now different developers in a development team may use different operating systems and still collaborate seamlessly. WSL 2 makes it even easier to run Docker on Windows. For developers using older Windows systems, Docker Toolbox makes it possible for them to use Docker. All in all, it just helps developers to focus more on development and less on maintaining the environment. **END** 🐧
