

Can AI Rescue the World from Global Warming and Climate Change?

Since last many decades, humans have been engaging in various activities that are directly or indirectly affecting the environment, releasing greenhouse gases, contributing to the rising temperatures, and more. However, the introduction of new technologies like artificial intelligence and machine learning is helping to fight against climate change and global warming.

Human civilisation will be at high risk by 2050 due to climate change, as reported by one of the Australian news media. Also, some recent reports suggest that Antarctica's Thwaites glacier is melting rapidly, and scientists are trying to understand how climate change is affecting glaciers using various techniques and models. It is also reported that glaciers in Kashmir are melting at an alarming rate, and the effect will be felt

not only in Kashmir but also in the entire Indus basin. Experts feel that mankind is running out of time, and we must come up with solutions to mitigate the global threat of climate change.

What contributes to climate change?

Before coming to solutions, we need to know the sources contributing to climate change. Starting from the first industrialisation, humans have been engaging in various activities that are

directly or indirectly affecting the environment, releasing greenhouse gases, contributing to the rising temperatures, and more. These activities include deforestation, burning of fossil fuels, and land and ocean pollution. Scientists have observed that the amount of carbon dioxide (CO_2) and some other greenhouse gases are steadily increasing in the atmosphere. Limiting some of the aforementioned activities could considerably reduce
