

Figure 2: Start service

Go to the *Settings* tab on the left panel and scroll down to find the *default options*.

Under *default options*, there is an extensive list of options to fine-tune your backup job. Click on *pick an option* and select the option you want to set. This option is added to a list where you can change the value of that option.

## Creating a new backup

To create a backup, click *Add backup* in the main menu. You can choose between configuring a new backup and importing from a file. With *import from a file*, you can import a configuration file that you exported earlier from the same computer or another computer running Duplicati. As there is no configuration file available and we want to specify all options, we choose the first option and click *Next*.

The wizard consists of five steps.

**Step 1:** Give the backup job a descriptive name and define the encryption settings.

**Step 2:** Specify the *Storage Type* you want to use for the backup and enter the URL, path and credentials.

Each *Storage Type* has its own requirements that you need to fill in. For an S3 compatible backend, you need to specify a *Bucket name*, *region*, and *storage class*. For other backends like Google Drive or Microsoft OneDrive, you need to create an AuthID token to grant permission to Duplicati for accessing that backend.
