Understanding Azure DevOps with a Hands-On Tutorial

DevOps is a mash-up of ‘development, operations, quality team, security team’. There are no set guidelines or methodologies available for the implementation of DevOps practices. In this article, we will take a hands-on look at Azure DevOps by implementing a sample Ionic Cordova application.

Agile has been the norm in several organisations for the last few years. The agile principles or Scrum methodologies have short sprints, usually lasting up to two to four weeks, and hence all activities in a software development life cycle need to be completed in this time period for the features that are to be delivered. Project teams usually struggle to deliver applications with better quality because of the short time available. Agile principles force you to develop, test, and deploy software within two to four weeks for specific features. The activities involved in development, test and deployment are manual. This results in missed deliveries, unsatisfied customers, unhappy developers, angry testers, perplexed project managers, concerned management, and escalations.

The implementation of DevOps practices using end-to-end automation with Visual Studio Team Services/Azure DevOps helps to achieve better quality and faster time to market.

DevOps is a mashup of ‘development, operations, quality team, and security team’. There are no set guidelines or methodologies available for the use of DevOps practices. It is a culture that consists of continuous practices, which help to achieve faster time to market for an application with the highest quality by continuous improvement and innovation. This is done by involving people, processes and tools.

Before we begin, let’s be clear about what DevOps is not:

- DevOps is not a methodology
- DevOps is not a process
- DevOps is not a tool or technology
