

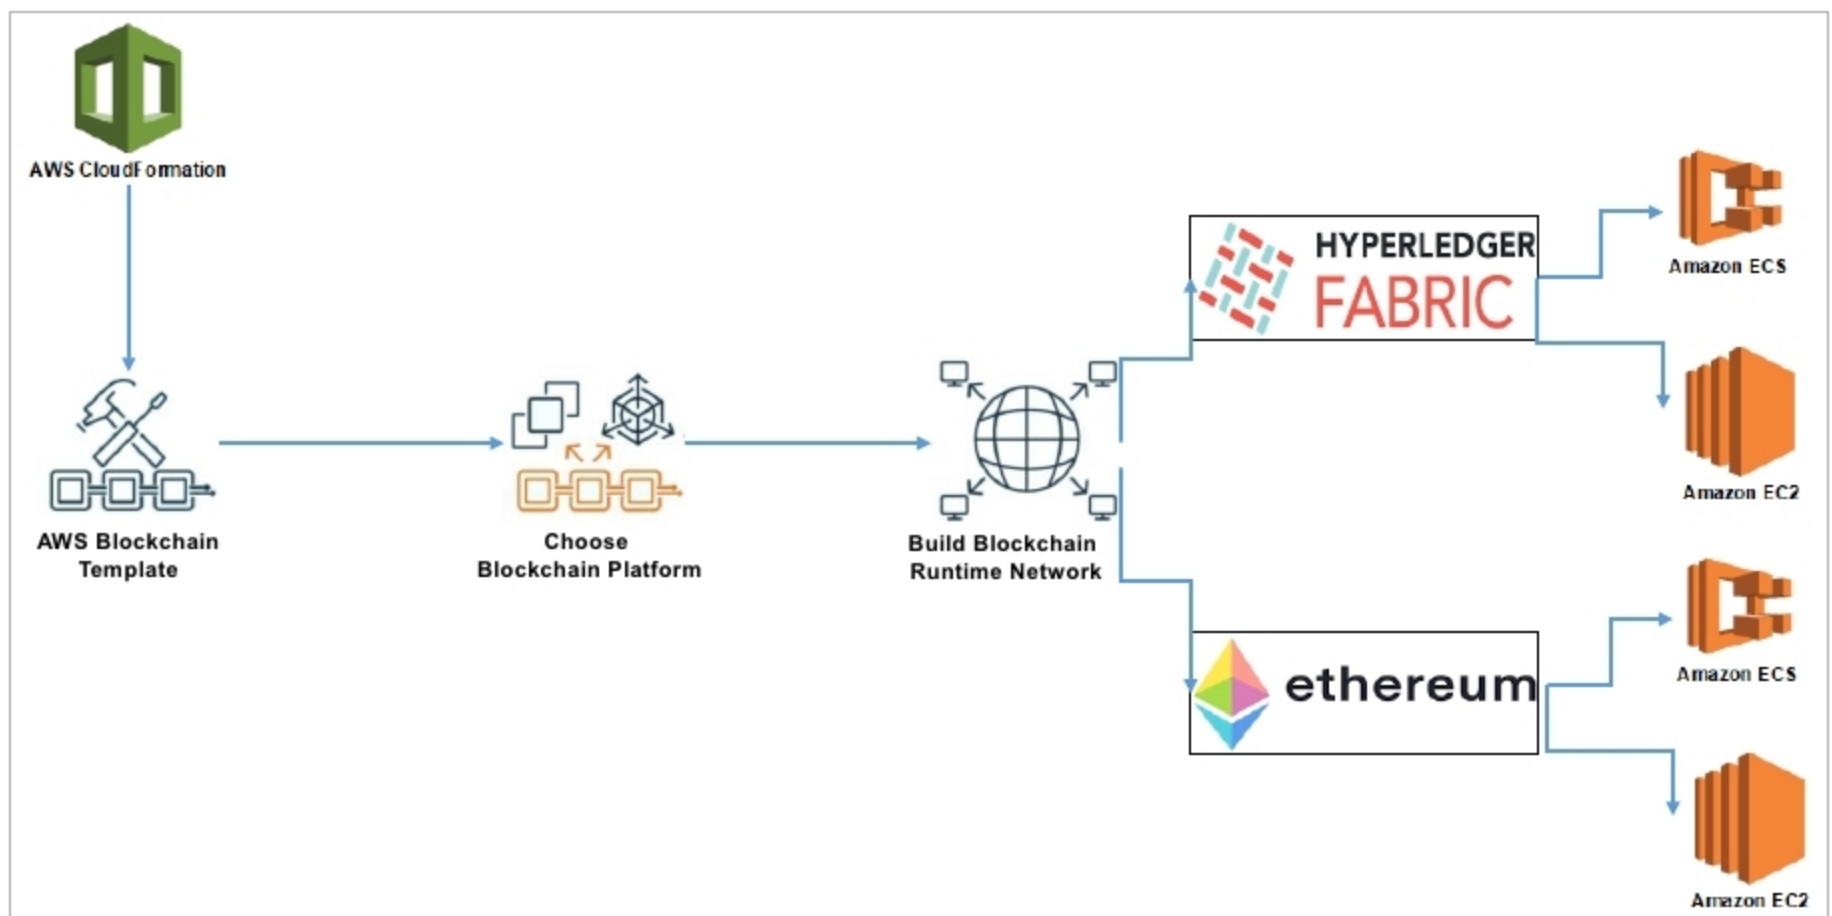

Figure 1: Life cycle of AWS blockchain template

manage and maintain your blockchain network. It manages your certificates and lets you easily invite new members to join the network.

Its features are:

- Fully managed, and provides the users to create the network in a few clicks
- Strong choice of Hyperledger Fabric or Ethereum
- Fully scalable and secure
- Reliable

AWS blockchain templates

Most cloud platforms provide blockchain service from one of the popular existing blockchain frameworks and do not define new blockchain services on their own. As an example, AWS provides blockchain service in two flavours — Hyperledger Fabric or Ethereum.

When using a blockchain platform service in the cloud, the setup, configuration and management of services should not turn into manual activities, and hence a ready-to-use blockchain service is always preferred. Most cloud platform-based blockchain services address this issue by providing pre-defined services.

AWS has pre-defined blockchain templates in the form of CloudFormation templates for building Hyperledger Fabric or Ethereum platforms in an EC2 instance or as a container in an ECS service, along with the required security features like VPC, IAM, and load balancer to get a complete blockchain platform service in a single-click activity. This ‘single pane of glass’ setup of AWS blockchain template, as shown in Figure 1, can integrate with AWS native monitoring services as well.

If you are proficient in AWS and new to blockchain or if you are an expert in blockchain and new to cloud platforms, the AWS blockchain template will help you to design and develop blockchain integrated cloud applications easily by combining the power of blockchain security features in Hyperledger Fabric or Ethereum with the power of the cloud in terms of scalability, agility, and reliability of platform services.

Since blockchain templates are inherited from CloudFormation templates, if you want to create a SaaS blockchain service like Corda later, you can create the services as a

container in ECS or an EC2 instance deployed service. You can prepare a CloudFormation template (in this case blockchain template) and make it available in a private marketplace so that it can be made reusable in future deployments as well.

Please note that the AWS blockchain template is available only in a few regions in the US, like Oregon, North Virginia, and Ohio. So when you are trying to use these services, please make sure that you choose the respective region for an application architecture to make use of them. If you are running a template in another region, it will launch the associated resource in the North Virginia region only.

Benefits of the AWS blockchain

For industrial solutions and real-time use-case development, blockchain templates are handy for the following reasons.

Faster deployment: Since blockchain services can be deployed using pre-defined templates, faster development and deployment are quite easy with the blockchain template, making it a faster ‘time to market’ enabled service.
