

An Introduction to Azure App Service

Azure App Service enables quick building, deployment and scaling of Web apps and APIs on the users' own terms. Users can work with .NET, .NET Core, Node.js, Java, Python or PHP, in containers or on Windows or Linux. It offers rigorous, enterprise-grade performance using a trusted, fully managed platform.

Platform as a Service (PaaS) is a cloud service model that provides different runtime environments in which a user can directly deploy applications. PaaS has a pay-as-you-go pricing model, features no upfront investment/capital expenditure, and has scalability and high availability. UI and CLI are available for managing PaaS and enabling a faster time to market, so that teams can focus on the core task of development.

Azure App Service is a popular PaaS solution offered by Microsoft

Azure. It is easy to configure, and all the configurations are available in the portal. Portal settings and UI change and improve constantly. A runtime stack is available with specific versions for Java, Python, .NET, and so on. Azure App Service can easily be configured with Azure Active Directory. It comes with multiple pricing models and some of the best features such as deployment slots or troubleshooting, notifications, scaling configurations, and so on. Azure App Service Environment is a premium service available that allows you to host Azure App Service in a virtual network;

hence, you can configure firewall rules and make it more secure. Azure App Service supports applications written in .NET, Node.js, PHP, Java, Python (on Linux), and HTML. It helps to host Web applications, mobile middleware or restful APIs.

Monitoring

The Azure App Service Overview section provides quick monitoring. Here you can get information related to the number of requests and average response time, data in, data out and HTTP 5xx errors. This helps to
