

Azure portal	The Microsoft Azure portal allows end users to create and manage cloud resources using a Web portal. This portal has been continuously improving for the past few years. End users can manage the dashboard as per their own wishes by pinning specific resources according to priorities.
Azure regions, geographies, availability zones	Microsoft Azure is available in more than 130 countries/regions. It helps to manage security, governance and compliance requirements. Each geography contains two or more regions. Each region has availability zones. Each availability zone has one or more data centres. Services or products are available based on regions; to verify this you can go to https://azure.microsoft.com/en-in/global-infrastructure/services/
Resource groups	Resource groups are logical containers in the Microsoft Azure portal. You can create a resource group that contains all the resources for a Web application, for a business unit or for a specific project that contains multiple modules. You can assign role based access to the entire resource group. By deleting a resource group, all the resources or Azure services in the group will be deleted.
Role based access control -- RBAC	Role based access control (RBAC) provides access management of Azure resources or resource groups. In a project or a business unit, if you want to provide access based on designation or a team's work profile then RBAC is very important.

detect issues related to unavailability of service due to a high number of requests or those related to slow response time.

Deployment slots

Azure App Service comes with a production slot. What if you want to isolate environments for different releases for different environments, such as dev or test or stage? The deployment slot feature helps you to create slots for different environments.

A deployment slot has its own host name and configurations.

With each deployment slot you get the following:

- Unique host name
- App content
- Configuration

The Standard, Premium, or Isolated tier in Azure App Service supports multiple deployment slots. Go to App Services and select your app. Click on *Deployment slots* -> *Add Slot*. Provide the slot a name, and select whether to

clone an app configuration (connection strings, language framework details, Web sockets, HTTP version, app settings, and so on) from another deployment slot or not. Click on *Add* -> *Verify new slot* in the *Deployment slots* section. Click on the new deployment slot to open that slot's page in the Azure portal. The deployment slot has its own host name, and is also a live app isolated from the production slot.

Deployment slots provide a feature that helps to swap slots in Azure App
