

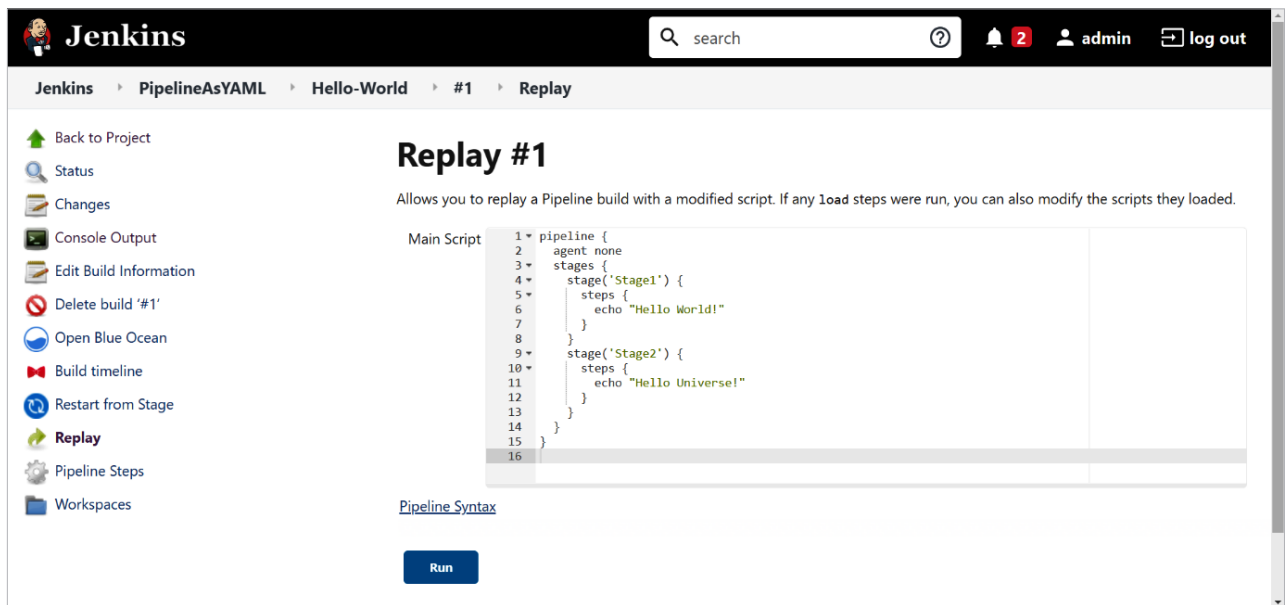

Figure 8: Replay pipeline

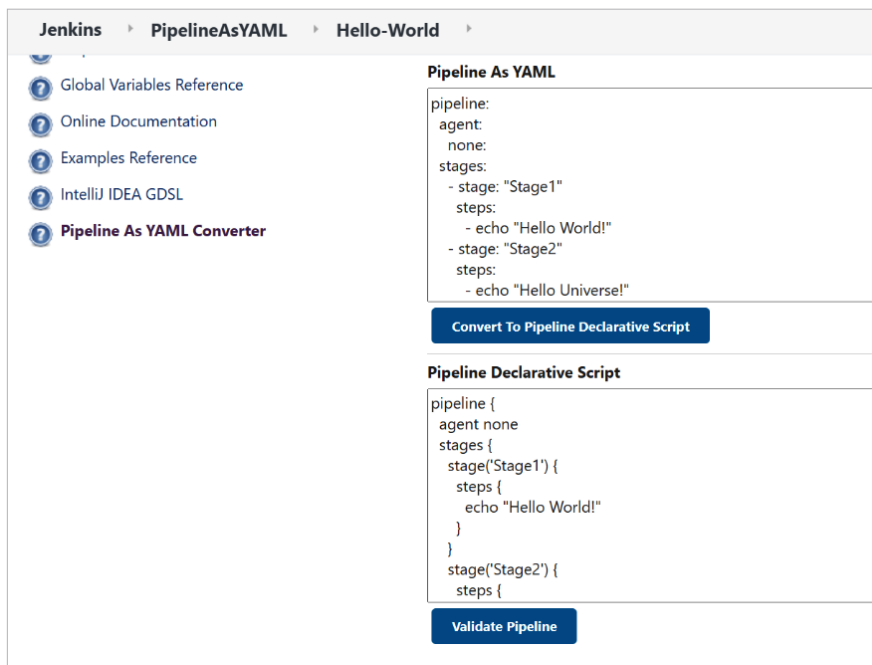

Figure 9: Valid pipeline declarative script

```
# Use 'sh' step for running
gradle commands
- *****
- stage: Build
  steps:
    script:
      - *****
# Define post actions
```

```
post:
  always:
    *****
```

Let's write a sample pipeline in YAML with two stages that display on-stage execution of messages.

Click on *Save* and then click on *Build Now*. Verify the *Console Output* and the messages based on the stage execution. Verify that the script available is not YAML script but pipeline in declarative syntax.

It is simple to verify the YAML pipeline script. Go to the newly created *Pipeline* and click on *Pipeline Syntax*. Next, click on *Pipeline As YAML Converter*. This helper aims to provide an easy way to convert pipeline as YAML into the pipeline declarative script format and also validate the pipeline declarative script. Enter your YAML script and click on *Convert To Pipeline Declarative Script*.

If the script is valid, then it will be converted in the declarative pipeline syntax (Figure 9).

If the YAML script is not valid, then an exception will be thrown. Click on *Validate Pipeline* to get more details on the exception and to check the issues (Figure 10).

Fix the issues and validate the pipeline again. Bingo! It is a valid YAML pipeline now, as pipeline conversion is successful (Figure 11).
