

In the previous sections, I have informed you of many commonalities shared within the DevOps tools ecosystem. But there is one more commonality that I was saving for last: *Automation*. Automation is the key driving force behind all the DevOps tools. We want to reduce our work by automating most tasks that require intensive and careful collaboration between various stakeholders.

This definition of automation in terms of DevOps is in complete synergy with the motive behind automation being done using AI/ML. Therefore, it is my opinion that AI will play a key role in the future of DevOps. It is inevitable. Most, if not all, DevOps tools will provide automation on a whole different scale with the power of AI.

But one thing that needs to be made clear before we end the article is that the rise of AI in the DevOps domain doesn't necessarily mean a massive reduction in jobs. In fact, it could be the other way around. Why? Because AI will simply convert into another 'in demand' skill for DevOps engineers (probably the most in demand). In order to handle DevOps, you will still require 'Devs' and 'Ops'. The medium of communication and collaboration between different entities can be automated, but the entities themselves cannot unless their jobs are completely redundant. Such jobs are a minority within the DevOps domain.

Key takeaway

If you are a DevOps engineer (or aspiring to be one), then this article is good news for you. The future isn't too far off. The second most 'in demand' skill after DevOps tools is Python for most DevOps jobs. Python is an absolute must for every data scientist, machine learning engineer and AI scientist. So if I were you, I would start using my spare time developing AI/ML skills. When the hammer comes down, as it always does, you will not only survive, but thrive.
