

Tenet	Description
Resource owner or user	You may have data stored somewhere in the cloud. For example, you may have uploaded some of your photos to Google, and may want to print them through a trendy app (e.g., an app that predicts how you will look at the age of 80). It is your photo. So, the photo is the resource, and 'you' are the user, who owns the resource.
Application or client	The photo app we just mentioned above is called a client, because it is an 'authorisation' client to the authorisation (OAuth2) server.
Resource server (server)	The server (physical, VM, container, pod), service or microservice stores the resource (in this case, the photo).
Authorisation server (auth server)	This is the server (physical, VM, container, pod), service or microservice that hosts OAuth2. It is always a best practice to keep the resource server separate from the auth server. The resource server is for supporting the resource management (say, through REST API or GraphQL), whereas the auth server is for authorisation only. This is like the present day doctors who specialise in one field. The concept of a general physician is passé.
Scope	This refers to the resource that accesses the application required to do its job. For example, the photo app needs to access your photos and camera.
Authorisation code / Key / Token	This is the first 'magic number' the application/client receives from the auth server in the process of authorisation.
Access token	This is the JSON Web token (JWT) format code application/client received from the auth server as a part of authorisation negotiation. This code application is saved inside a safe vault, and passes on every resource request to the resource server for authorisation, through the <i>https</i> header.
Lease / Expiry / Timeout	Every access token comes with a lease for some time; e.g., it may be valid for a day. Beyond that it becomes invalid.
JWT	This format of access token – the JSON Web token – will be discussed in detail later on.
