

Figure 3: Android Studio: Naming the project *coronavirus_tracker*Figure 4: Android Studio: Naming the package *com.example.coronavirustracker*

- Update the 'Package Name' as shown in Figure 4, if needed, or let it be the default name. This package name will work as *ApplicationId*, which is used to identify the app uniquely on the device and on the app stores. Developers can also select or deselect the Android and iOS support in the project on this page.
- Click on 'Finish' to initialise the project.

API-nCov2019 v2.0.0

The *coronavirus_tracker* app uses free of cost API-nCov2019 v2.0.0 to get the Covid-19 data, which is shown in Figure 5. This API is provided by

- Nubentos S.L, an API marketplace for the digital healthcare sector. To use its services, visit the API Store and select API-nCov2019-2.0.0 [<https://store.nubentos.com/store/apis/info?name=API-nCoV2019&version=2.0.0&provider=admin>]. Register and login to use the services.
- Go to the *Application* tab under the *Main Menu* and create a new application, or use a previous one to test the API, as shown in Figure 6.
 - In the *Main Menu*, go to the *API* section and then to the *API console* under the sub-menu.

Select the application built in the first step (*coronavirus tracker* in this case). Use the sandbox option while testing, which is shown in Figure 7.

- Check the endpoint descriptions and select which one to use according to the app needs (Figure 8). Try it out to get further insight, as depicted in Figure 9.

When two systems interact, the API provides a solution/protocol to communicate between them. Endpoint simply is one touch point end of that communication channel, and is a URL pointing to a resource on the server.

API-nCov19-v2.0.0 exposes 11 endpoints for use. These are:

- GET/ cases
- GET/ todayCases
- GET/ active
- GET/ deaths
- GET/ todayDeaths
- GET/ recovered
- GET/ critical
- GET/ casesPerOneMillion
- GET/ deathsPerOneMilion
- GET/ totalTests
- GET/ testsPerOneMillion

Each endpoint supports Covid-19 data of numerous countries, along with total world Covid-19 data. The Coronavirus tracker app lists a number of countries, providing an easy UI to users and reducing the effort in typing country names.

Developing the *coronavirus_tracker* mobile app

Project overview

- Assets:** This folder contains the images used in *coronavirus_tracker*. The sub-folder 'w2560' contains images of the national flags of various countries, which are used to make the UI more visually attractive.
- lib:** This folder contains *main.dart*, which acts as the framework endpoint for the application. When the app is compiled, it finds the *main()* function on which the
