

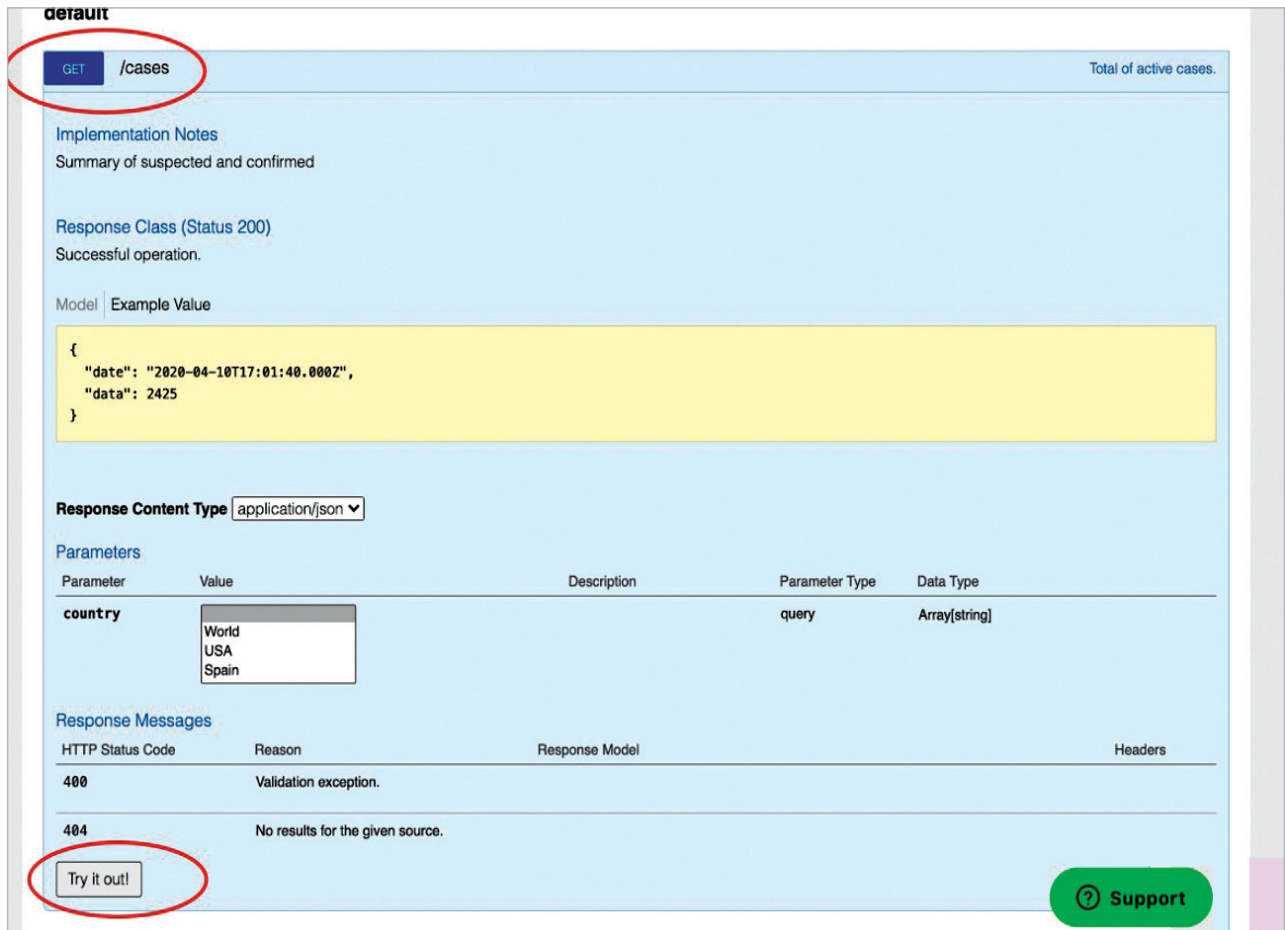

Figure 8: API-nCov19: Endpoint description page

- **Future<int> getEndPointData ForQuery():** This method is an extension of the above method, by adding parameters to the endpoint, and gets the specific data by country and endpoint.
 - **api_keys.dart:** This contains *APIKeys* class, implementing only one parameter *nCovSandboxKey*, which is used in the *API* class.
 - **gitignore:** Ignores *api_keys.dart*, for security measures.
- **helper_functions:**
 - **number_representation.dart:** This file has a single function, which trims the integer data received from the API to the nearest thousand (K), million (M), or billion (B).
- **modal:**
 - **new_card_data.dart:** This file implements the 'NewCardData' data model class, which contains only the class constructor with the parameters *image*, *title*, *cases*, *today*, *active*, *death*.
- **views:**
 - **home_page.dart:** Contains the *HomePage* class inheriting stateful widget, which helps in changing the state of the UI when new data is received.
- **country_page.dart:** This page is navigated to show more detailed data about a country. The app bar contains the title *Country Name*. The body contains the national flag and the data for Covid-19 fetched from the API using the above given endpoints. Data points include *Cases*, *Today's Cases*, *Active Cases*, *Deaths*, *Today's Deaths*, *Recovered*, *Critical*, *Cases Per One Million* and *Deaths Per One Million*.
- The project described using the above folders and files is structured as shown in Figure 12. There are two pages in the app, namely, 'HomePage' and 'CountryDataPage'. These pages are built using default and custom widgets. The green boxes in Figure 12 are the components of the layout, under the body of

 **Note:** Flutter has an inbuilt *setState()* method, but developers can choose from a variety of options using libraries like *Provider* or *Getx*, for state management. Almost all the code for our *HomePage UserInterface* resides here in the widget build method.
