

Combining DevSecOps and the Cloud to Transform an Organisation

This article covers the DevSecOps transformation framework and its phases, mapping it to DevSecOps tools on the cloud. It also highlights the benefits of and the best practices for using DevSecOps.

DevSecOps is about introducing security early in the software development life cycle (SDLC) by expanding the collaboration between the development and operations teams to include security teams. This set of concepts, cultural philosophies, practices, team organisation structures and tools increases an organisation's ability to deliver applications and services at high velocity to its clients. It helps in responding to new requirements quickly, as well as to problems that occur in production. This enables organisations to serve their customers better and compete more effectively in the market.

DevSecOps aims to maximise the predictability, efficiency, security and maintainability of operational processes. It helps in building security into application development from end to end.

Organisations need to understand the relationship between DevSecOps and cloud computing. DevSecOps is about improvement in software development processes and culture, while cloud computing is about technology and services. Organisations need to understand the value that both can bring, when combined, to achieve their transformation objectives.
