

sent within the local network by substituting ARP responses. Arpspoof is an effective tool for sniffing traffic. IP forwarding or Internet routing by the kernel must be enabled earlier.

Stress testing

The main objective of every stress testing tool is to put the tested application or system under conditions where its security may be compromised and give an opportunity for a successful attack. For example, we can replicate a state in which the software is so overloaded that it creates a time window for an attack or injection of malware. Two useful tools for stress testing are briefly described below.

DHCPig: Written in Python with the use of the Scapy network library, it is a good script for starting a DHCP exhaustion attack. DHCPig utilises

all IP addresses present on the local network, thus forbidding new users from acquiring them. To use DHCPig, we need admin rights and the Scapy network 2.1 or higher.

Funkload: Funkload is also written in Python. It is a toolkit that works as a load web-tester, and performs various operations on the server such as load testing and functional Web project testing. It can also be used for detecting weak spots in a tested Web application, finding bugs that weren't caught during testing, and scrutinising an application's recoverability.

Some other tools for stress testing are MDK3, SlowHTTPTest, t50, etc.

Kali Linux is an exceptionally useful tool that every penetration tester should be familiar with. While it provides a notably rich set of tools for every stage of the penetration testing

process, the final choice of tools to use depends on the tasks and goals of the project. Under different situations, the same tools can show completely diverse levels of accuracy and efficiency.

In the article, we have gone through the ways we can use Kali Linux for penetration testing, and also seen some of its most popular and frequently used tools for penetration testing. For more details, do visit the Kali Linux official site. **END!**
