

SODA Foundation and SNIA team up to advance education for data and storage management

The SODA Foundation and Storage Networking Industry Association (SNIA) have entered into a marketing alliance to move towards the common goal of increasing education for a unified framework, and standardisation for data and storage management. The SODA Foundation is an open source project under the Linux Foundation that seeks to foster an ecosystem of open source data management and storage software for data autonomy. SNIA works towards developing standards and education programmes to advance storage and information technology.

Steven Tan, VP & CTO, Futurewei and SODA Foundation Chair, said, “Working with SNIA in a marketing capacity is an ideal stepping stone to combining our expertise for the advancement of storage management technology. Together, we will contribute to creating a more engaged and informed developer ecosystem and emphasise the importance of the standardisation of storage management APIs.”

The alliance facilitates a marketing collaboration to promote the SODA Foundation and SNIA standards through educational content. This will include webcasts, social media, email campaigns, newsletters, and inclusion in news and events.

Michael Oros, executive director, SNIA, said, “The goal of this alliance is to educate our respective communities on the importance of open source storage management standards and lay the groundwork for future collaborative technological developments, particularly leveraging SNIA’s work developing the SNIA Swordfish specification. We are excited to be working closely with the SODA Foundation and look forward to the results of our joint efforts.”

Availability of open source data and rise of cyber threats are likely to drive the market demand significantly. Social media platforms accumulate data pertaining to location, community, interests, and likes for informing government agencies of any possible threats.

The report added, “The use of relevant information on organisations based on employee experience and devoid of reputation management firms can drive the market. Actionable insights on people and companies for sensitive information are likely to be witnessed in the coming years. Organisations can glean data in real-time from a wide range of sources for gaining awareness and performing location-based investigations. Quantification of risks, events, and consequences can assist decision makers. But large volumes of data lakes and lack of skilled personnel can hinder market growth.”

The COVID-19 pandemic has driven people to stay within the limits of their homes and has increased Internet usage. Greater reliance on blogs, discussion forums, vlogs, and other digital platforms can bode well for the OSINT market. OSINT tools can accumulate data from these sources to predict future trends.

The report said that remote working has created the challenge of malicious attacks by cybercriminals. This can be overcome with the help of OSINT tools. Intelligence agencies can gain useful insights from public resources and overcome any potential threats to nations.

Guardicore unveils IPCDump, an open source tool for tracing interprocess communication on Linux

Guardicore has announced the availability of IPCDump, a new open source tool for tracing interprocess communication on Linux. It said that the tool covers most interprocess communication (IPC) mechanisms, including pipes, fifos, signals, UNIX sockets, loopback-based networking, and pseudoterminals. It is useful for debugging multi-process applications and gaining transparency into how they communicate with one another in their IT environment.

Guardicore VP of Research Ofri Ziv said, “IPCDump is the natural by-product of our talented R&D team’s efforts to push the technical boundaries of our segmentation platform. Rather than let it go to waste, our team wanted to show our commitment to the development and security communities by sharing a useful open source debugging tool.”

Modern applications have distinct processes that plug into one another in a black box, creating significant challenges for developers when something breaks.
