

This issue is particularly true for debugging complex multiprocess applications. IPCDump solves this problem by tracing both the metadata and contents of apps' communication, and tracing IPC between short-lived processes.

Security practitioners can also use the open source tool to explore how business apps communicate with internal and external systems. IPCDump can also easily track short-lived processes' creation and destruction, a tedious task that typically requires security and IT teams to check port numbers against netstat manually. It comes with support for pipes and FIFOs, signals (regular and real-time), UNIX streams and datagrams, and pseudoterminal based IPC. It also comes with event filtering based on process PID or name, and human-friendly or JSON-formatted output.

CloudLinux releases AlmaLinux Beta

AlmaLinux, the open source enterprise-level Linux distribution created as an alternative to CentOS, has been released in beta with most RHEL packages and is ready for community testing. A stable release is planned for the end of Q1 2021.

CloudLinux's founder and CEO, Igor Seletskiy, said, "As promised, the main development and maintenance were done by the CloudLinux team. And now we appeal to the community for its contributions. In the spirit of the community-driven initiative, we now require assistance with testing, documentation, support and planning the future roadmap."

LF Networking launches open source project Anuket

LF Networking (LFN) has announced the creation of the Anuket project. A merger of CNTT (Cloud Infrastructure Telco Taskforce, which provided reference models and architectures for both virtual machine and containerised network functions) and OPNFV (Open Platform for NFV, which reduced time to integrate and deploy NFV infrastructure and onboard VNF/CNFs), Anuket tools and artifacts will help the global communications community to deliver compliant network services faster, more reliably and securely, and accelerate the transformation to cloud native infrastructures.

Heather Kirksey, vice president of community and ecosystem development at the Linux Foundation, said, "It's incredible to see the evolution of what began as the Open Platform for Network Functions Virtualization over six years ago. With Anuket, we are making it easier and more efficient for CSPs to transform their networks and save money, with one, end-to-end platform."

Anuket delivers standardised reference infrastructure specifications and conformance frameworks for virtualised and cloud native network functions. By continuing OPNFV's legacy of operating upstream with collaboration across other open source projects (such as LF Networking, LF Edge, CNCF, LF AI, ODIM and other industry organisations and standards bodies) and CNTT's operator focus, the project ensures technology meets business and operational needs. Anuket will also preserve CNTT's close working relationship with GSMA, and the latter will continue to publish the project's Reference Model work.

The project will build on the long-standing success of each community's output. OPNFV's final stand-alone release, Jerma, delivered in December 2020, delivered CNTT-ready capabilities.
