

## Open source FIDO server to enable passwordless authentication

StrongKey, the leading provider of cryptographic key management solutions, has announced the availability of a free, open source FIDO server, which will enable developers to easily integrate passwordless authentication into their Web applications.

StrongKey's FIDO server features the latest FIDO2 standard and delivers secure, public key cryptography based authentication to enable a future where passwords are replaced with biometrics.

Cyber security and regulations pertaining to user privacy are increasingly becoming complex. StrongKey's open source FIDO server will help meet regulations by removing passwords and password storage, thus enabling application creators and software companies to protect user data for compliance.

FIDO successfully protects against phishing, session hijacking, as well as man-in-the-middle and malware attacks, sources at the California based company claimed.

Arshad Noor, CTO, StrongKey, said, "Removing passwords has become a critical necessity in the light of today's cyber threat environment. Since FIDO represents the industry's best path towards finally removing the long-standing problem with shared secrets, we've decided to contribute our FIDO server to the open source community for the betterment of everyone."

Alissa Knight, senior analyst, cyber security practice, Aite Group, added, "By using FIDO2 protocols, which are quickly becoming the industry standard, companies can offer customers the latest and strongest multi-factor authentication possible. The availability of free, open source, community-supported, standards-compliant FIDO2 server software makes it easy to integrate data security and privacy into existing or new authentication systems."

The open source FIDO server is available on GitHub. This project is currently licensed under the GNU Lesser General Public License v2.1.

## Linux Foundation's ELISA Project will help build Linux based safety-critical systems

The Linux Foundation has announced an open source project to create a shared set of tools and processes to help companies build and certify Linux based safety-critical applications and systems.

The project, called the Enabling Linux in Safety Applications (ELISA), will make it easier for companies to build safety-critical systems such as robotic devices, medical devices, smart factories, transportation systems and autonomous driving using Linux, sources at the Foundation said.

Founding members of ELISA include ARM, BMW Car IT GmbH, KUKA, Linutronix, and Toyota. According to the Foundation, as there was no clear method for certifying Linux, companies were finding it difficult to demonstrate that their Linux based systems meet the necessary functional safety objectives.

"All major industries, including energy, medical and automotive, want to use Linux for safety-critical applications because it can enable them to bring products to market faster and reduce the risk of critical design errors. The challenge has been the lack of the clear documentation and tools needed to demonstrate that a Linux based system meets the necessary safety requirements for certification," said Kate Stewart, senior director of strategic programmes at The Linux Foundation.

"Past attempts at solving this have lacked the critical mass needed to establish a widely discussed and accepted methodology, but with the formation of ELISA, we will be able to leverage the infrastructure and support of the broader Linux Foundation community that is needed to make this initiative successful," she added.

As part of the project, the Linux Foundation will work with certification authorities and standardisation bodies in multiple industries to establish how Linux can be used as a component in safety-critical systems.

The project will also define and maintain a common set of elements, processes and tools that can be incorporated into Linux based, safety-critical systems amenable to safety certification.

Additional project goals of ELISA include:

- Developing reference documentation and use cases.
- Educating the open source community on safety engineering best practices and the safety community on open source concepts.
- Enabling continuous feedback from the open source community to improve processes, and to automate quality assessment and assurance.
- Supporting members with incident and hazard monitoring of critical components relevant to their systems and establishing best practices for member response teams.

## Tata Elxsi develops intelligent automation framework using open source technology

Tata Elxsi – a global design and technology services company and a part of the Tata Group – and Portuguese media company NOS, have announced the launch of an intelligent automation framework for communication service providers.

Built using open source technology, Tata Elxsi's Digital Operations Transformation Toolbox (DOTT 2.0) offers an intelligent operations automation framework for user-defined service definition, zero touch provisioning, validation and scheduling of field partners for provisioning and testing scenarios.
