

It also provides an extensible roadmap for service rollout and monitoring use cases, enabling communication service providers to launch new services rapidly.

“With the right blend of our rich domain knowledge and Tata Elxsi’s design, technology and digital capabilities, we have developed a framework that blends the existing and next-gen technologies for faster and cost-efficient service delivery for our customers and us,” said Judite Reis, director of network operations at NOS.

The digital operations transformation toolbox enables provisioning of existing services through redefined simplified processes and allows the capability to achieve speedy completion of new service launches. This toolbox replaces the earlier complicated operational procedures that used disparate systems, thereby bringing down costs and reducing process latencies significantly.

For example, digital provisioning services such as IP VPN, which took several hours for completion earlier, can now be automated and be completed under 30 minutes.

“We are delighted that our design and technology services have helped NOS achieve its digital transformation and customer satisfaction goals. Tata Elxsi’s DOTT 2.0 framework has helped in bringing significant productivity gains, the capability to launch services faster and generate additional revenues. In addition to operations automation, we have also integrated our user design tool to make existing processes more intuitive, easy-to-use and future ready,” said Rajagopalan R., deputy CTO and head of network transformation technologies, Tata Elxsi.

US cyber security leader Imperva open sources Active Directory Java SDK

Imperva, a leading global provider of best-in-class cyber security solutions, has released the source code to Domain Directory Controller (DDC), an Active Directory (AD) Java software development kit (SDK) designed to simplify AD interaction for small, medium and large projects.

Unlike Java’s base LdapContext, this library makes use of Apache Directory LDAP to simplify work such as managing primary/secondary server connections, query pagination, and automatic reconnection attempts, *InfoQ* reported.

DDC also provides an abstraction API over the top of the LDAP query syntax. This API provides an enumeration of Active Directory fields, giving developers an easy and statically-typed way of building working queries.

Sterlite Tech to build near real-time controllers for 5G using open source code

Data network solutions company Sterlite Tech will be contributing to the O-RAN Alliance, a global carrier-led consortium that promotes the software based extensible Radio Access Network (RAN).

Building on a foundation of virtualised network elements and standardised interfaces that embrace higher levels of embedded intelligence and openness, Sterlite Tech will contribute to and leverage reference designs developed by the O-RAN Alliance, the Pune based company said in a statement.

The company will be using open source code to build a near real-time controller and distributed units, with white box hardware. It will also contribute code and results from field trials for 5G technology.

“As a contributor to the O-RAN Alliance, Sterlite Tech is committed to evolve RANs (radio access networks). With our Programmable, Open,

BMW open sources RAMSES – a 3D rendering system

BMW has released the source code of its project RAMSES (Rendering Architecture for Multi-Screen EnvironmentS) under the GENIVI in-vehicle infotainment alliance.

RAMSES implements a distributed system for rendering 3D content with a focus on ensuring high performance in terms of bandwidth and resource consumption.

The code, written in C++, is licensed under the MPL 2.0 (Mozilla Public License).

According to *KTelegram*, RAMSES is designed to optimise the rendering of content from the entertainment systems, containing several screens. It is a layer that applies a client-server model for the rendering. One process generates the 3D content and the other process is engaged in its rendering. Rendering can be performed on another device or in a virtual environment.

RAMSES provides piping around existing OpenGL implementations, which allows one to apply the proposed model of distributed rendering for all OpenGL applications. It supports different versions of OpenGL (OpenGL ES 3.0+, OpenGL 4.2, 4.5, etc), allowing developers to use one code base on different platforms that provide different OpenGL versions.

RAMSES also provides its own low-level API, which encapsulates and packages the commands and resources to minimise traffic between the client and the server. This allows the transmission of high-quality 3D content over conventional networks for display, without delays and gaps.
