

system. This is a relatively easy task when they are provided by an *RPM* package. *RPM* packages include shared library dependency information within the package meta data.

The *yum whatprovides* command can identify the package that provides a particular library. Let's suppose the name of the missing library is *libpthread.so.0*. Then execute the following command:

```
# yum whatprovides libpthread.so.0
```

The output of the above command will be somewhat similar to what's shown below:

```
glibc-2.17-196.el7_4.2.i686 : The GNU libc libraries
Repo      : rhel-7-server-rpms
Matched from:
Filename  : /lib/libpthread.so.0
```

The output above indicates that the *glibc* package contains the library that is being looked for.

If the shared library is not packaged and distributed by Red Hat, the third party vendor will have to be called to see if it can be provided

Note: Whenever a shared library is installed or removed from the system, make sure to run the *ldconfig* command without any argument. This will update the runtime linker cache */etc/ld.so.cache*.

I have summarised below what needs to be performed whenever you are installing a third party application on RHEL systems:

- Execute the *ldd* command to find out what libraries are missing:

```
# ldd /usr/sbin/app
```

- Note down the names of missing libraries from the above output.
- Now find the name of the package that provides that library by using the *yum whatprovides* command:

```
# yum whatprovides <missing-library-name>
```

Note down the name of the package. Let us suppose the name of the package is *abc*.

- Now install the *abc* package so that you can get the respective libraries.
- The final step is to execute the *ldconfig* command without any arguments to update the runtime linker cache. **END** 🐧
