

## Cloud Native Computing Foundation welcomes Apple as a platinum end-user member

Apple has joined the Cloud Native Computing Foundation (CNCf), the home of open source projects like Kubernetes and Prometheus, as a top-level platinum end-user member.

With this, Apple joins 87 other CNCf end-user members like Adidas, Atlassian, Box, GitHub, The New York Times, Reddit, Spotify and Walmart.

As part of Apple's platinum membership, Tom Doron, senior engineering manager at Apple, has joined CNCf's governing board. By becoming a CNCf end-user member, companies also join the Linux Foundation, according to TechCrunch.

Apple has long been a pioneer in cloud native computing and is one of the earlier adopters of container technology. Apple has also contributed to several CNCf projects, including Kubernetes, gRPC, Prometheus, Envoy Proxy and Vitess, and has hosted the FoundationDB Summit at KubeCon + CloudNativeCon last year.

"Having a company with the experience and scale of Apple as an end-user member is a huge testament to the vitality of cloud native computing for the future of infrastructure and application development," said Chris Aniszczyk, CTO of the Cloud Native Computing Foundation.

The platinum end-user members meet every month and advise the CNCf governing board and technical oversight committee on key challenges, emerging use cases, and areas of opportunity and new growth for cloud native technologies.

a Wind River Linux subscription that provides access to long-term support and maintenance, including security updates, for the fully upstream Wind River Linux content.

Shane Coughlan, general manager, OpenChain, commented, "Our relationship with Wind River includes a strong focus on ensuring real world solutions for real world challenges. Welcoming Wind River as the first OpenChain 2.0 conformant organisation is a natural and exciting expansion of our collaboration."

## Microsoft buys Pull Panda to improve code review workflows on GitHub

Microsoft-owned GitHub has acquired Pull Panda, a US based startup that makes collaboration tools for software teams, for an undisclosed amount.

The company plans to use Pull Panda's tools to create more efficient and effective code review workflows on GitHub.

The year-and-a-half old Pull Panda helps thousands of software teams work together on code and improve their processes by combining three features: Pull Reminders, Pull Analytics and Pull Assigner.

- Pull Reminders notify developers that a collaborator needs their review.
- Pull Analytics provides real-time insight into the effectiveness of a team's process.
- Pull Assigner automatically distributes code across teams.

All three tools are now available for free in the form of a single GitHub Marketplace application called Pull Panda. In future, GitHub plans to integrate these features directly into its code hosting platform.

Microsoft is discontinuing Enterprise Plan subscriptions but will continue to support existing Enterprise Plan customers through its on-premises offering.

All paid subscriptions have been converted to free subscriptions effective June 17, 2019.

New users can install Pull Panda for their organisations for free from the company's website or GitHub Marketplace.

Pull Panda's founder and creator, Abi Noda, wrote in a blog post, "Joining GitHub will allow our products to be fully integrated and offered to millions more developers around the world. I will be joining the GitHub team to integrate Pull Panda, and continue to grow its features as part of the core product."

Open source repository hosting service GitHub was acquired by Microsoft in June 2018 for US\$ 7.5 billion.

## Google releases TensorNetwork, an open source library for efficient tensor calculations

To deal with the complexity of quantum systems, scientists use data structures called tensor networks. These structures enable them to focus on the quantum states that are most relevant for real-world problems while ignoring other states that aren't relevant.

However, widespread use of tensor networks in the machine learning community is hindered by the following reasons:

- A production-level tensor network library for accelerated hardware has not been available to run tensor network algorithms at scale.
- Most of the tensor network literature is geared toward physics applications and creates the false impression that expertise in quantum mechanics is required to understand the algorithms.
