

Payments company Square open sources its code

US based digital payments firm Square has announced that it will open source its Bitcoin cold storage solution, as mentioned in the blog post by Square security engineer Alok Menghrajani.

The documentation, code and tools for the company's Subzero Bitcoin cold storage solution are now available at GitHub for its users. Square's move was aimed at inspiring innovation in the cryptocurrency sector and to help startup companies with potential to fulfil their security needs. Subzero uses a hardware security module (HSM), which is designed to run a custom Bitcoin wallet implementation called Subzero Core.

Menghrajani added, "We hope that by sharing our work, we can make it easier for others to fulfil their security needs, enabling even more innovation—and better protection for all players—in the cryptocurrency space. In the long run, since we had to solve problems that other companies may face, we are interested in standardising some of our work."

Menghrajani went on to state that because the underlying HSM is programmable, Square developed a technology that is capable of switching Bitcoin from a hot wallet to the cold storage at any time. The program requires multi-party signatures before bringing the cryptocurrency back to the hot wallet.

"The HSM is programmable, allowing us to support Bitcoin wallets today while giving us the flexibility to implement other protocols in the future," he said.

SUSE gets OpenChain certification

SUSE has announced that it has got OpenChain certification, an initiative that can make licensing of open source more understandable, predictable and efficient, for software supply chain participants. SUSE becomes the first enterprise Linux distributor that is certified as conforming with the OpenChain Project Specification. For this, SUSE is assisting by offering free industry resources to focus on innovation by reducing complex processes.

The OpenChain Project is the industry standard to manage open source compliance across the supply chain. It helps in identifying and sharing key

components of high quality open source licensing programs. The OpenChain Project establishes confidence in open source software by making things more efficient, simpler and consistent.

Commenting on the development, Thomas Di Giacomo, CTO, SUSE, said, "For more

than 25 years, SUSE has created and engaged with open source communities as a foundation for its enterprise solutions. We always engage with the community to better meet customer needs, and our OpenChain certification is another indication to enterprises that we are committed to making their experience with open source software more reliable and cost effective."

Ralf Flaxa, president of engineering at SUSE, said, "Securing OpenChain compliance was a logical step for SUSE, as OpenChain provides an industry format that documents our existing research and development (R&D) process that we have refined over many years. With so much of our engineering efforts tied to openSUSE and many other open source communities, programs such as OpenChain will enable us to ensure we are using equivalent terminology and guidelines so that more time is spent on innovation and less on process."

The OpenChain certification is supported by the newly published Open Source Policy of SUSE, which publicly shares its long-time values, guidelines and procedures for the development and engagement of open source software.

Open source integration for NVIDIA's RAPIDS software by Kinetica

Kinetica is a US based company that develops a distributed, in-memory database management system using graphics processing units. The company has announced that it will be making open source code available to RAPIDS open source software for integration. RAPIDS is a new machine learning training stack introduced by NVIDIA.

The union of Kinetica with RAPIDS will help data scientists and data engineers to work on artificial intelligence by exploring, training, visualising, and integrating machine intelligence into smart analytical applications. This will help in accelerating the computing power of the GPU.

Today, AI is the main strategy for enterprises, so it is very important to streamline data science and data engineering processes. RAPIDS boosts the power of NVIDIA GPUs, which minimises AI model training time from days to minutes.
