

Kinetica combines a GPU database, real-time analytical techniques (location intelligence, time series, text search), and the ability to run analytics and pre-trained machine learning models in the database. Combining RAPIDS and Kinetica provides enterprises with a concrete way to realise the end-to-end impact of AI, whether it is when driving cars, stocking warehouses, or making personalised recommendations.

Kinetica and RAPIDS run seamlessly on the GPU and communicate without copying data to the CPU, because Kinetica integration is based on the Apache

Arrow project. Very soon Kinetica will make Apache Arrow integration code available to developers through GitHub. RAPIDS and Kinetica can be downloaded from the NVIDIA GPU cloud.

“We’re excited to support Apache Arrow, a

core component of accelerated analytics on the GPU. Our latest open source capabilities enable us to seamlessly integrate with RAPIDS across the GPU-powered data ecosystem. While NVIDIA drives model development and training, Kinetica drives operationalisation and deployment of those models in-database, so enterprises gain maximum insight from their data,” said Nima Negahban, co-founder and CTO of Kinetica.

“Companies are increasingly data-driven, but speed is of the essence to use this data,” said Jeffrey Tseng, head of product for AI infrastructure at NVIDIA. “With RAPIDS and Kinetica, enterprises can leverage the power of the GPU and advanced analytics across the model development toolchain and dramatically simplify and speed up the data science pipeline,” Tseng added.

Over 50 per cent of cloud developers contribute to open source, claims survey

About 55 per cent of cloud developers said that they contribute to open source projects and 37 per cent of them would contribute more if their companies provide them the time to do so, a survey by DigitalOcean, a provider of cloud infrastructure software and services has concluded.

Corporate leaders seem to be sending mixed signals to their developers about

open source software, as per the survey, which was conducted by DigitalOcean on a sample size of 4,300 cloud developers.

Around 71 per cent of developers said that their companies expect them to use open source software as part of their daily

development work. Yet, the majority of employers are not very supportive when it comes to developers contributing software to the FOSS ecosystem if it doesn’t have a direct benefit for the company. Just 34 per cent of the respondents were given time to work on open source software projects that were not related to the company’s work, the survey noted.

Edgeworx open sources ioFog platform

Edgeworx, an edge computing startup based in Silicon Valley, California, exited its stealth mode and announced the availability of its open source ioFog platform. It will be getting funding from Samsung NEXT, Sequoia Seed and CloudScale Capital Partners, the announcement mentioned.

As per company reports, Edgeworx ioFog allows users to “bring their own edge” by enabling any device or hardware to become a secure software platform. The company aims to hit the edge computing market.

Targeting developers, ioFog makes it simple to deploy and manage any application or containerised microservices at the edge. Edgeworx has design security for both hardware and software at the edge rather than repurposing security models originally designed for the cloud, which resolves customers’ security concerns.

The ioFog platform focuses on three foundational technologies for developers:

- It turns hardware into an intelligent edge node by providing an edge compute platform that standardises running software at the edge.
- It monitors the health and resources so that users can operate at the edge effectively at scale.
- It also makes it easy to create a dynamic, distributed, self-organising edge compute network with all devices.

The platform also creates a distributed trust network by constantly validating a comprehensive set of security signals to provide pure edge security. Every device secures the edge network. Instead of increasing attack surface, users get an increased defence surface.

The ioFog platform is open sourced under the Eclipse Foundation, turning any Linux device into an edge software platform.
