

After running the command, two new files (*index.wasm* and *index.js*) will get added to the working directory. These files hold the WebAssembly module and its glue code, respectively.

Step 3: Loading WebAssembly code in the browser

Now, we are in familiar Web development territory. We can create a basic *index.html* file and include the JavaScript glue code in a script tag.

```
<!DOCTYPE html>
<html>
  <head>
    <meta charset="utf-8">
    <meta http-equiv="X-UA-Compatible" content="IE=edge">
    <title>WebAssembly Example</title>
    <meta name="viewport" content="width=device-width,
initial-scale=1">
  </head>
  <body>

    <!-- Include the JavaScript glue code. -->
    <!-- This will load the WebAssembly module and run its
```

```
main. -->
    <script src="index.js"></script>

  </body>
</html>
```

Once we are done with the compilation of the above code and have created the *.wasm* file, we can place the three files (*index.wasm*, *index.js* and *index.html*) in the document root of any working Web server and call *index.html* in a browser to test it.

This article has covered what WebAssembly does, how it works and how it fits into the Web, along with a simple example. The ability to run fast, low-level code in the browser will give way to new apps and Web experiences not possible with JavaScript alone. **END** 🐧
