

Top Ten Linux Commands *for* Systems and Network Admins

The command line interface is a very potent tool in Linux. It helps systems and network admins execute different tasks seamlessly. Here is a list of the top ten Linux commands that can simplify their work.

One of the best things about GNU/Linux is that it is highly configurable through the command line interface. One can manage all of GNU/Linux via the command line. This makes automation really simple, which is why GNU/Linux is so popular among systems administrators. In this article, we will discuss the top ten commands for GNU/Linux systems administrators.

In the first section of this article, we cover commands that can be used to query hardware information; the second section discusses network related commands, and the last section covers miscellaneous commands.

Querying hardware information

Finding out the CPU architecture details: We often need to find out details about the CPU's architecture, such as its byte order, CPU mode, number of cores/threads, caches, virtualisation support, and so on. GNU/Linux provides a handy command called *lscpu*, which provides insights

about CPU architecture. Given below is the sample output of the command:

```
$ lscpu
Architecture:          x86_64
CPU op-mode(s):        32-bit, 64-bit
Byte Order:            Little Endian
CPU(s):                4
On-line CPU(s) list:   0-3
Thread(s) per core:    2
Core(s) per socket:    2
Vendor ID:              GenuineIntel
```

 **Note:** Some part of the output is not shown here, to save space.
