

Wiwynn introduces edge platform based on open source technologies

Taiwanese cloud IT infrastructure provider for data centres, Wiwynn, has launched an edge platform that is based on the open source hardware technologies of Nokia.

The Edge Platform 100 (EP100) is considered as a 3U edge system, and is equipped with Nokia-led OCT OpenEDGE specifications that deliver power to applications requiring low latency and huge data processing capabilities.

The platform supports up to five 1U half-width servers. In addition, it can flexibly configure with 1U full-width and 2U half-width server sleds. Besides, the communication service providers can enhance their computing power by including additional EP100 systems for applications that range from regional central offices to base stations.

EP100 has the chassis-based power management systems and supplies that provide power efficiency and simple management for edge sites.

Wiwynn is creating a software stack with OpenBMC, OpenRMC and Open System Firmware (OSF) to optimise the management for open systems. The company will also contribute the firmware development kit to attract more ecosystem partners to connect and innovate upon it.

Commenting on the development, Dr Sunlai Chang, senior VP and CTO, Wiwynn, said, “We are thrilled to embrace edge cloud opportunities in the 5G era by applying Open Compute Project (OCP) hardware and initiating an open firmware development kit.”

He added, “Wiwynn EP100 enables communication service providers to address diverse low-latency data processing demands of cloud RAN and modern central offices with a flexible and high-efficiency architecture at a balanced cost.”

Hannu Nikurautio, head – cloud RAN product management, Nokia, said, “Nokia AirFrame open edge which was launched in April 2018 welcomes Wiwynn’s adoption of the Nokia led OCP OpenEDGE specification, with this announcement of a new equipment provider for enclosure and sled designs.”

VIPPOOL releases open source software to develop systems using the blockchain

VIPPOOL clerk is a server-side application that offers functions as a normal Web API and can be accessed more easily through VIPPOOL storage.

VIPPOOL Inc. has announced the launch of the open source release of VIPPOOL clerk, a software used for developing systems by leveraging blockchain technology. In addition, the company has introduced VIPPOOL storage, a Python library developed to make the software simple to use.

With VIPPOOL clerk, a user can easily read from or write data to blockchains, without having specialised knowledge of the technology. The software runs on the Google App Engine platform and enables users to quickly get information about the balance, transactions, etc, related to blockchains. This can be done in a scalable way by pre-processing blockchain data.

In addition, the software has the ability to develop a new transaction even without sending the private key to the server. This is because the electronic signature is performed on the client’s side.

The latest software runs in VIPPOOL, a mining pool for Monacoin, which is managed by the company. This pool boasts of the world’s largest hash rate, and can be connected to the APIs previously released, without any of the hassles of setting things up. VIPPOOL clerk has been released as open source software; therefore, it can be easily reworked for other blockchains.

VIPPOOL storage is a Python library that makes the VIPPOOL clerk even simpler to use. By just implementing a few lines of code, one can get different types of information on Monacoin and its testnets, like the remitted currency, or read/write data.

Apart from proposing proofs of concepts (PoCs) to the software users, VIPPOOL Inc. plans to link the software to private-key management hardware that the company wants to sell in the near future.
