

Setting Up Qt on Raspberry Pi and its Basic Application

This project describes the steps to get started with Qt software on the Raspberry Pi operating system. Qt is a platform-independent application that can run on all desktop and mobile operating systems (OSes), in addition to most embedded OSes—including Linux Embedded, Windows Embedded, QNX, vxWorks and Integrity—with one technology and one codebase. When developed, the application can run across multiple platforms at near-native performance. Thus, Qt saves a lot of development time and, hence, minimises time-to-market.

Qt is well-documented and has extensive API functionality, high-end graphics and integrated development tools. It has all that is needed to make the creation of embedded applications easy.

Hardware required for building an embedded application on Qt is as follows:

1. Raspberry Pi 3 board
2. Touchscreen or computer monitor
3. USB keyboard and mouse
