

Develop a Simple App at Super Speed with Flutter

Mobile apps are a craze nowadays and one that works both on iOS and Android can be made very easily, given the right tools. In this article, two young tech enthusiasts explain how they built an app which works both on iOS and Android in just two days, using Flutter. Doing it by conventional methods would have been tedious, but with Flutter it was a breeze.

There's an app for everything these days. People come up with new ideas everyday but few of these actually make it in the market place. Let's imagine that you are developing an app that is going to be the next big thing. You spend hundreds of hours to build a beautiful material UI, with fluid transitions and animations that look very pretty. You make a solid impression with your friends who test your app. Now it's time to go face the real world. Your app makes it to the Google PlayStore.

You quickly realise that you are missing out on a big audience. Apple users have found your app cool, but they can just see it and not get it. You now have to make a different version for iPhone. That shouldn't take long, right? Unfortunately, it isn't that simple. Porting from a completely different software ecosystem is hard and will double the development time. Maintaining it would be a nightmare. A patch needs to be applied to both the versions. You either need to be a really good Android and iPhone developer, or you need to get someone who can help you do it.

What if you had a way to write code just once, and it automatically became available for both iOS and Android?

Enter Flutter – the gateway to creating better and faster apps.

Flutter is an open source software development kit that has been built to solve this very problem. Flutter applications are written in Dart, which was brewed at home at Google. “But why Dart?” The Flutter team researched dozens of languages and finally ended up with Dart, finding it the perfect match for designing the UI, using the same principles as Flutter. Dart is the real reason why developers love Flutter.

Dart is object-oriented, easy to look at and has AOT (Ahead of Time) and JIT (Just in Time) compilation capabilities. Dart makes it super easy to create smooth animations at 60 FPS.

With it, users can easily design the layout with Flutter without needing to use something like XML or JSX. Just one language to stick to! And it's a cakewalk to get used to the language.
