

```

],
declarations: [
  ChatDialogComponent
],
exports: [ ChatDialogComponent ], // <-- export here
providers: [ChatService]
})
export class ChatModule { }

```

You need to jump over to the *app.module.ts* file and import the *ChatModule* there. All you have to do is add it to the *import* section. After the import, the *app.module.ts* file should look like what's shown below:

```

import { BrowserModule } from '@angular/platform-browser';
import { NgModule } from '@angular/core';
import { AppComponent } from './app.component';
import { ChatModule } from './chat/chat.module';

@NgModule({
  declarations: [
    AppComponent
  ],
  imports: [
    BrowserModule,
    ChatModule
  ],
  providers: [],
  bootstrap: [AppComponent]
})

export class AppModule { }

```

Now we can go into *app.component.html* to delete the default code, and we'll declare our chat dialogue component there:

```
<chat-dialog></chat-dialog>
```

If you pull up the app, you should see that the chat dialogue component works.

Introducing Dialogflow

To start building chatbots in Dialogflow, go ahead and sign up. Dialogflow is a completely free service. You don't have to enter any kind of billing information to create your first agent on it.

The fundamental purpose of the Dialogflow agent is to detect the intent of the user. When a user asks a question and if the chatbot has been trained to recognise this phrase, it will detect the intent. You can program the bot to run backend code at this point, or just send a response down to the user.

When the bot doesn't recognise the intent, then you can have it respond with any kind of customised message. Dialogflow allows you to customise this in many different ways. In this tutorial, I'm going to focus on the back and forth

dialogue between the user and the bot.

You need to add a phrase that the user might say. In addition, you need to add multiple phrases to make your bot more robust to different ways of expressing this intent. The bot sends a response once it recognises this intent.

That is how we build a basic chatbot with Dialogflow.

Getting to understand Small Talk

Small Talk allows you to quickly customise the personality of your bot without having to create your own custom intents. Small Talk has a huge list of possible scenarios and you can add your own custom language to it.

Small Talk is a great way to impress your users by adding funny or intelligent responses to certain common questions.

Grabbing a client access token

Before you leave Dialogflow, you need to grab a client access token. To grab the token, click on the agent, and then from the main agent page, just copy the client access token.

Now, go back into Angular and add that client token inside your *environment.ts* file (Figure 4).

In some cases, it's not secure to add an API key here, but since Dialogflow is free and doesn't have write access, this isn't an issue.

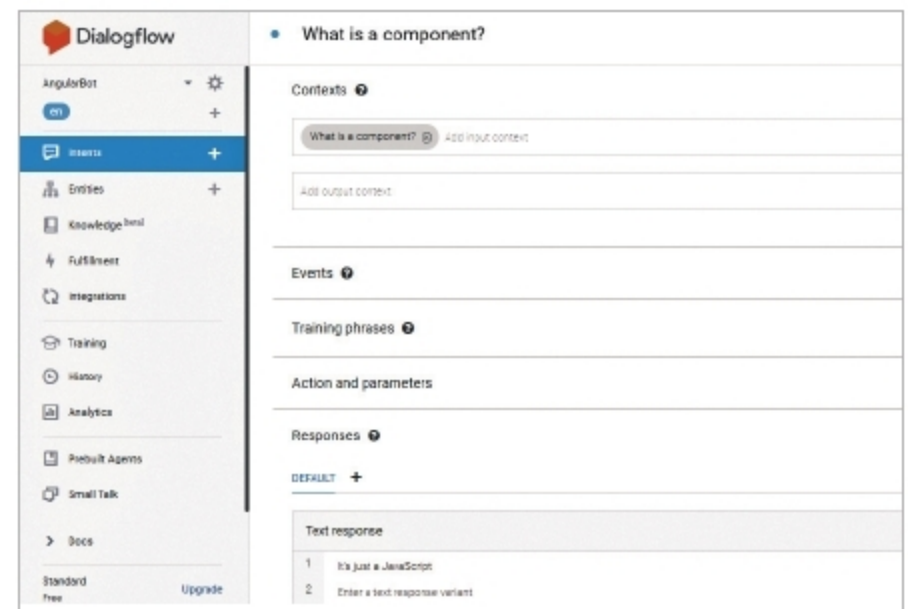

Figure 1: A Dialogflow agent tries to match the utterance to a particular intent

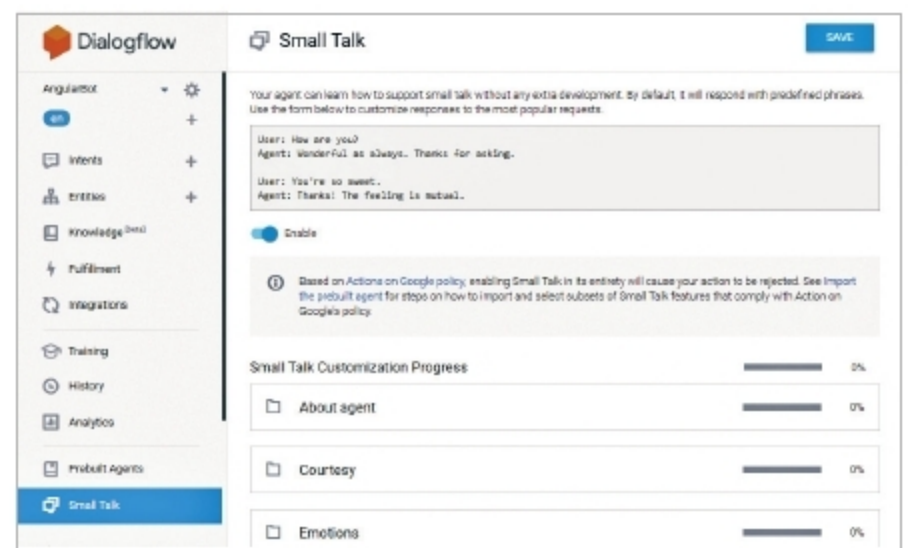

Figure 2: Small Talk helps to get started with agent and conversation design faster
