

intracellular calcium dynamics. Every system component, excluding cameras, lenses and pumps, is 3D printed. Since the designs of all components are open source, any laboratory can use the designs to create a similar tool.

The researchers calculated that this could save other labs about US\$ 20,000, compared with commercially available products.

Along with the designs for the system components, the team open sourced the code of its MATLAB-based RHYTHM software for signal processing.

While a previously released version of this software allowed for analysis of action potential duration, generation of activation, and phase maps, the updated version, RHYTHM 1.2, analyses several additional parameters of voltage and calcium recording.

“Our laboratory maintains an open data policy,” said professor Igor Efimov of GW, who also heads the Human Physiology Lab at MIPT.

“Not many research teams nowadays can afford the expensive equipment for optical mapping. Now they can use our designs to recreate an affordable system just like the one we used. And they can process the data with RHYTHM. A further advantage of our tool is that it offers the freedom to design new experiments on diverse samples,” he added.

Paragon releases Microsoft NTFS for Linux

Paragon Software Group, a leading data storage expert, has announced the release of Microsoft NTFS for Linux. This is a unique combination of drivers for NTFS and HFS+ file systems that are accessible from a Linux environment.

The new tool is easy to install as well as uninstall. The user can simply run the install.sh and uninstall.sh scripts that will perform all the required operations to create the driver, install it, and remove and deactivate it from the platform.

The latest tool by Paragon boosts the performance of users by opening direct access to the partitions that they earlier had difficulties accessing from Linux. However, the rate of transfer is similar for native Linux file systems and even better in some cases. For better file system integrity, the HFS+ file system and its native journaling support can be used while transferring the files between a Linux PC and a Mac. In addition, Microsoft NTFS for Linux by Paragon Software enables the users to format any volume as HFS+ or NTFS, check the formatted volumes for integrity and fix errors.

Microsoft NTFS for Linux is a part of the File System Link (FSL) driver technology of Paragon that is available for licensing to embedded system providers and original equipment manufacturers (OEMs). The FSL technology can be used to solve incompatibility issues between different file systems and operating systems.

NTFS or New Technology File System was first released with Windows N and is much more modern, reliable and stable than FAT or FAT 32. The file system was specifically designed to be used with the Windows OS.

Broadband Forum launches open source USP agent to enhance IoT interoperability

Broadband Forum has announced an open source User Services Platform (USP) agent to facilitate the connected home and accelerate interoperable Internet of Things (IoT) deployments.
