

- Blockchain doesn't require passwords because it relies either on biometric data or on private keys as well as multiple steps for authentication, to ensure that users are who they say they are. These systems provide more effective protection to our information than user names, passwords, etc.

The rise of smart devices and other largely autonomous technologies has also exposed us to high levels of hacking. The Internet of Things has provided another route to hacking that is less prone to early detection, and hence may give rise to phishing scams. Experts are now relying upon blockchain technology to recognise invalid or potentially corrupt commands and inputs, and to prevent the shutting down of a system's functionality completely.

Data is a universal currency. A single consumer's data is worth at least US\$ 240 per day and likely much more, according to one source. Storing data in a centralised database is reckless these days, as it can easily be attacked by hackers. The blockchain is decentralised by nature, which means there is no single point of penetration for hackers to invade.

We are living in the age of cyber warfare, which is more dangerous than a ransomware intrusion against a corporation. The federal government of USA was the target of 61,000 cyber attacks in 2017, each of varying levels of danger. High-level blockchains are known for their excellent security features and can limit the damage caused to infrastructure

by cyber intrusion. Blockchain DNA cyber defence security systems will provide a new state-of-art cyber defence system.

Finally

Blockchain is not just about cryptocurrencies anymore. The blockchain adoption rate is growing extremely fast globally, across multiple industries.

As cyber attacks become inevitable, security professionals have to find new solutions to tackle cyber miscreants. Blockchains have drawn worldwide attention for their ability to create highly transparent and secure systems for such purposes as transferring money. Forging entries in a blockchain based distributed ledger is extremely difficult, since data is shared by everyone in the system rather than stored on a single computer. **END** 🐧
