

Lost or deleted files are a common phenomenon. To ensure file and folder security, prudence dictates you take a backup. To avoid the drudgery of physically doing so every now and then, it is best to automate the process. The author has created a Python program for just such a situation.

We often create new documents, files and folders in our computers. Sometimes we accidentally or mistakenly delete documents. Consider that you have made an important presentation after spending a lot of time on it. But accidentally, your computer hard disk crashes. It is a painful situation. People often take a backup of files. But it is very difficult to back up after every one hour or after every minute. So, to overcome this problem, I am going to demonstrate a Python script that I've created, which will keep taking backups of your file or folder after a specified period of time (specified by you). The name of the program is *sync.py*. It is for Windows and is compatible with Python 2 and Python 3.

The program contains the following three files:

Sync.py: The main program

Sync1.ini: The configuration file

Logger1.py: The module for logger support

Sync.log is a file created by the *sync.py*.

Let us now understand the code of *sync.py* and look at how it works.

1. Import the essential library to be used.

```
Import configparser.  
Import time.  
Import shutil.
```
