

operations by providing a single infrastructure management tool designed to help enterprise DevOps and IT operations manage complexity, while improving visibility and control of IT assets,” said Gerald Pfeifer, vice president of products and technology programs, SUSE.

IT managers can leverage SUSE Manager 3.1 to deliver container images across development, test and production environments. It is also possible to support the DevOps continuous/integration deployment model using the latest tool. Moreover, customers can reduce their workloads on development, testing and production in a container, with the new SUSE Manager.

“SUSE Manager’s new container management and compliance capabilities will enable customers to automate orchestration and provisioning of their container-based services while ensuring container compliance from the same tool they are already using to manage their Linux infrastructure,” said Mary Johnston Turner, research vice president for enterprise system management software, IDC.

SUSE Manager 3.1 is available for multiple cloud solutions provided by Amazon Web Services, Google Cloud and Microsoft Azure. It comes with a 60-day free trial along with patches and updates for two months.

Chrome OS gets new power management settings

Chromebook owners can now finally keep their machines awake even when the lid is closed. Google is upgrading the Chromebook experience by adding new power management settings to control the behaviour of Chromebook’s lid.

Google developer François Beaufort has shared the screenshot of the new power management settings in a Google+ post. The screenshot highlights the settings for controlling power management behaviour. “We can control whether our device goes to sleep or stays awake when the lid is closed and choose between ‘Turn off display and sleep’ (default), ‘Turn off display’ and ‘Keep display on’ when idle,” explains Beaufort.

The new power management controls are available in the latest Canary channel, so you can test these settings on your Chromebook from the Canary experimental channel. If you don’t want to install the testing version, you can download the ‘Stay Awake’ Chrome extension to enhance power management.

Python 3.6 becomes a supported version for Ubuntu 17.10

Canonical has made Python 3.6 a supported version for the upcoming Ubuntu 17.10 (Artful Aardvark) release. The latest development emerges amid the ongoing Python 3.6 transition, which aims to deliver an advanced programming experience to Ubuntu users.

“Python 3.6 is now a supported version in the Artful release, and almost all the packages that build C extensions have been rebuilt,” Canonical’s development team wrote in a blog post.

While Canonical engineers have developed the Python supported version for the next Ubuntu version, there are still some failures. Nevertheless, there are plans to make Python 3.5 the default version. Canonical’s team is also in the process of making the Netplan project available, by default, on Ubuntu 17.10. This removes the clutter in the networking configuration of the open source platform and enables a unified way to configure a network.

Ubuntu 17.10 is scheduled for release on October 19, this year. Alongside the Python 3.6 support and Netplan implementation, the platform will include Linux kernel 4.13 to improve the current computing model.

Baidu releases open source deep learning benchmark tool to measure inference

Baidu Research, a division of Chinese Internet giant Baidu, has released its open source deep learning benchmark tool. Called DeepBench, the new solution comes with inference measurement.

As an upgrade to the initial DeepBench version that was released in September last year, the new technology offers a better understanding of the performance of inference that works with multiple chips and neural networks. The development also provides new kernels to train from available deep learning models. The results for training and inference are available across a variety of processors.

“With the addition of the ability to measure inference, researchers will now have a more comprehensive benchmark for the performance of their AI hardware,” said Sharan Narang, systems researcher, Baidu Research Silicon Valley AI Lab.

DeepBench benchmarks fundamental operations to solve the benchmarking inference issue. “Measuring inference is critical. It covers the operations needed to run neural networks on a device, be it in the cloud, on a phone or a wearable,” Baidu’s researcher Dr Greg Diamos reported.

Baidu Research conducted an internal study that revealed DeepBench’s performance in real-time. The tool established a 16-bit floating point for multiplication and a 32-bit floating point for addition for training operations. Similarly, it established an 8-bit fixed point for multiplication and a 32-bit fixed point for addition.

You can access the updated DeepBench code on GitHub. The online repository also includes documentation to help you deploy the deep learning benchmark tool for your next project.
