

- Now the designing part is complete. So let's write some logic for these controls. Return to Eclipse and create one class named *MainViewController* under the package *application.view*. This will be our controller class for FXML, which means that it will contain the logic for our controls.
- Now copy the following code in the auto-generated *Main.java* and *MainViewController.java* classes.

Main.java

```
package application;

import javafx.application.Application;
import javafx.fxml.FXMLLoader;
import javafx.stage.Stage;
import javafx.scene.Scene;
import javafx.scene.layout.BorderPane;

public class Main extends Application {
    private BorderPane mainLayout;

    @Override
    public void start(Stage primaryStage) {
        try {
            primaryStage.setTitle("My First ");
            primaryStage.show();
            FXMLLoader loader = new FXMLLoader();
            loader.setLocation(Main.class.getResource("view/
Main.fxml"));
            mainLayout = loader.load();
            Scene scene = new Scene(mainLayout);
            primaryStage.setScene(scene);
            primaryStage.show();
        } catch (Exception e) {
            e.printStackTrace();
        }

        public static void main(String[] args) {
            launch(args);
        }
    }
}
```

MainViewController.java

```
package application.view;

import javafx.fxml.FXML;
import javafx.scene.control.Button;
import javafx.scene.control.TextField;

public class MainViewController {
    @FXML private TextField textfield; //will be used in
    fx:id
```

Figure 4: Output of the application

```
@FXML private Button button; //will be used in
fx:id

public void getText(){
    System.out.println("Text entered is " + textfield.
getText());
}
```

- Now save the above two files and come back to Scene Builder. Go to the controller area under the *Document* section and select *application.view.MainViewController* from the *Controller* class drop down menu.
 - Open the hierarchy area again and select *Button* on the interface, then type 'button' in the *fx:id* field under the code area in the *Inspector* section. This is the ID that we have written earlier in the controller class. Through this ID, code will connect to this button on the interface. Also, select *getText* from the *On Action* drop down menu. This implies that on the click of this button, this action will be called from the controller class.
 - Repeat this step of assigning the *fx:id* to textfield control as done in step 3 for *textfield*.
 - Now save everything and run your *Main.java* file as a Java application, type some text and click the button. The same text will be printed on the console window.
- Try this with different combinations and have fun!
- In this way, you can create complex applications and interfaces with the help of Scene Builder without actually coding your controls.

Scene Builder has certainly given a boost to Java, which had begun losing popularity, and is definitely the future for developing enterprise applications. The main advantage of using Scene Builder is that it gets timely updates, which incorporate the latest controls in its library.
