

data review of Docker adoption. The following highlights of this study should answer all your questions.

i) *Docker adoption has increased 40 per cent in one year*
At the beginning of March 2016, 13.6 per cent of Datadog's customers had adopted Docker. One year later, that number has grown to 18.8 per cent. That's almost 40 per cent market-share growth in 12 months. Figure 7 shows the growth of Docker adoption and behaviour. Based on this, we can say that companies are adopting Docker very fast and it's playing a major role in global digital transformation.

ii) *Docker now runs on 15 per cent of the hosts*
This is an impressive fact. Two years ago, Docker had about 3 per cent market share, and now it's running on 15 per cent of the hosts Datadog monitors. The graph in Figure 8 illustrates that the Docker growth rate was somewhat variable early on, but began to stabilise around the fall of 2015. Since then, Docker usage has climbed steadily and nearly linearly, and it now runs on roughly one in every six hosts that Datadog monitors.

iii) *Larger companies are leading adoption*
Larger companies tend to be slower to move. But in the case of Docker, larger companies are leading the way since the first edition of Datadog's report in 2015. The more hosts a company uses, the more likely it is to have tried Docker. Nearly 60 per cent of organisations running 500 or more hosts are classified as Docker dabblers or adopters.

Figure 9: Larger companies are leading adoption

Figure 10: Orchestrators are taking off

Figure 11: Adopters quintuple their container count within nine months

While previous editions of this report showed organisations with many hosts clearly driving Docker adoption, the latest data shows that organisations with mid-sized host counts (100–499 hosts) have made significant gains. Adoption rates for companies with medium and large host counts are now nearly identical. Docker first gained a foothold in the enterprise world by solving the unique needs of large organisations, but is now being used as a general-purpose platform in companies of all sizes.

iv) *Orchestrators are taking off*

As Docker increasingly becomes an integral part of production environments, organisations are seeking out tools to help them effectively manage and orchestrate their containers. As of March 2017, roughly 40 per cent of Datadog customers running Docker were also running Kubernetes, Mesos, Amazon ECS, Google Container Engine, or another orchestrator. Other organisations may be using Docker's built-in orchestration capabilities, but that functionality did not generate uniquely identifiable metrics that would allow us to reliably measure its use at the time of this report.

Among organisations running Docker and using AWS, Amazon ECS is a popular choice for orchestration, as would be expected — more than 35 per cent of these companies use ECS. But there has also been significant usage of other orchestrators (especially Kubernetes) at companies running AWS infrastructure.

v) *Adopters quintuple their container count within nine months*
The average number of running containers Docker adopters have in production grows five times between their first and tenth month of usage. This internal-usage growth rate is quite linear, and shows no signs of tapering off after the tenth month. Another indication of the robustness of this trend is that it has remained steady since Datadog's previous report last year.

vi) *Top technologies/companies running on Docker technology*

The most common technologies running in Docker are listed below.

1. **NGINX:** Docker is being used to contain a lot of HTTP servers, it seems. NGINX has been a perennial contender on this list since Datadog began tracking image use in 2015.
