

Google releases open source platform Spinnaker 1.0

Google has released v1.0 of Spinnaker. The new open source tool is designed for the multi-cloud continuous delivery platform.

The search giant started working on Spinnaker back in November 2015 along with Netflix. The tool was aimed at offering large companies fast, secure and repeatable production deployments. It has so far been used by organisations like Microsoft, Netflix, Waze, Target and Oracle.

The Spinnaker version 1.0 comes with a rich UI dashboard and offers users the ability to install the tool on premise, on local infrastructure and the cloud. You can run it from a virtual machine as well as using Kubernetes. The platform can be integrated with workflows like Git, Docker registries, Travis CI and pipelines. It can be used for best-practice deployment strategies as well. "With Spinnaker, you simply choose the deployment strategy you want to use for each environment, e.g., red/black for staging, rolling red/black for production, and it orchestrates the dozens of steps necessary under-the-hood," said Christopher Sanson, the product manager for Google Cloud Platform.

Google has optimised Spinnaker 1.0 for Google Compute Engine, Container Engine, App Engine, Amazon Web Services, Kubernetes, OpenStack and Microsoft Azure. The company plans to add support for Oracle Bare Metal and DC/OS in upcoming releases.

the new development offers you a completely open source solution for monitoring vital health signs.

The HealthyPi board comes with an Atmel ATSAMD21 Cortex-M0 MCU that is compatible with Arduino Zero, and can monitor health signs like ECG and respiration. Additionally, there is a pulse oximetry front-end along with an LED driver and 22-bit ADC. The board includes a three-electrode cable that has a button and stereo connector.

Through the available 40-pin header connector, HealthyPi can connect with your Raspberry Pi 3. There is also a USB CDC device interface and UART connector that enables connectivity with an external blood pressure module.

It is worth noting here that the HealthyPi is not yet a certified medical device.

Microsoft Azure gets an open source tool to streamline Kubernetes developments

Microsoft has announced the first open source developer tool for Azure.

Called Draft, the new tool is designed to help developers create cloud-native applications on Kubernetes.

Draft lets developers get started with container-based applications without any knowledge of Kubernetes or Docker.

There is no need to even install either of the two container-centric solutions to begin with the latest tool.

"Draft targets the 'inner loop' of a developer's workflow — while

developers write code and iterate, but before they commit changes to version control," said Gabe Monroy, the lead project manager for containers on Microsoft Azure, in a blog post. Draft uses a simple detection script that helps in identifying the application language. Thereafter, it writes out simple Docker files and a Kubernetes Helm chart into the source tree to begin its action. Developers can also customise Draft using configurable packs.

The Azure team has specifically built Draft to support languages that include Python, Java, Node.js, Ruby GO and PHP. The tool can be used for streamlining any application or service. Besides, it is well-optimised for a remote Kubernetes cluster.

Monroy, who joined Microsoft as a part of the recent Deis acquisition, highlighted that hacking an application using Draft is as simple as typing 'draft up' on the screen. The command deploys the build in a development environment using the Helm chart.

The overall packaging of the tool is similar to Platform-as-a-Service (PaaS) systems such as Cloud Foundry and Deis. However, it is not identical to build-oriented PaaS due to its ability to construct continuous integration (CI) pipelines.

You can access Draft and its entire code as well as documentation from GitHub. The tool needs to spin up a Kubernetes Cluster on ACS to kickstart the new experience.

Toyota starts deploying Automotive Grade Linux

While Apple's CarPlay and Google's Android Auto are yet to gain traction, Toyota has given a big push to Automotive Grade Linux (AGL) and launched the 2018 Toyota Camry as its first vehicle with the open source in-car solution. The Japanese company is set to launch an AGL-based infotainment platform across its entire new portfolio of cars later this year.

"The flexibility of the AGL platform allows us to quickly roll out Toyota's infotainment system across our vehicle line-up, providing customers with greater connectivity and new functionalities at a pace that is more consistent with consumer
