

Events

A powerful feature of the Ubidots platform is to set alerts on your sensor data. For example, we can raise an alert in case the temperature goes over 30°C. If that condition is met, we can deliver the alert via email or SMS, invoke a Webhook, etc.

To configure a sample event, you can go to the Web portal and click on *Events*. Then add a new event, select the device and variable, and define the condition as shown in Figure 9. For example, we have selected the temperature variable for device *D1* and set a condition of > 30°C (greater than 30 degrees Centigrade). The graphical configuration is shown in Figure 9.

Click on *Continue* and you will be asked to select the medium via which the alert can be sent. The list of delivery channels is shown in Figure 10.

Click on *Finish* to create the event, and then the alert will be raised on any sensor value for a temperature that is above 30°C from device *D1*.

Client libraries

You can integrate the API calls for ingesting data into the system via various client libraries that are made available in Ubidots. Client libraries are available for multiple popular languages like Python, Java, Node.js, Ruby, Android and others. This makes the task of collecting any sensor data from an application straightforward, removing the burden of dealing directly with HTTP request/response handling in your code.

The API methods are not just to save values but also for creating data sources (devices), creating variables, getting values of variables and for the bulk import of variable values.

A sample code in Python for ingesting values is given below:

```
from ubidots import ApiClient

api = ApiClient(token='<API_TOKEN>')

# Get Temperature Variable
my_variable = api.get_
```

Figure 9: Event condition configuration

Figure 10: Event notification channel configuration

```
variable('<VARIABLE_ID>')
```

```
# Save Temperature Variable
new_value = my_variable.save_value({'value': 29.5})
```

Ubidots' pricing

Ubidots has flexible pricing. There

are two plans available: Education and Business. The Education plan is free and lets you connect up to a maximum of 20 devices, allows data retention for 30 days and a maximum sensor data ingestion rate of 60 per minute. This should be sufficient for most hobbyists and enthusiasts who want to get started with the platform. The Business plan caters to a greater number of devices, an on-demand ingestion rate and a management suite. The pricing is available on call. You can find out more about the differences between the Education and Business plans on the pricing page.

Ubidots is a powerful hosted IoT platform that provides features to ingest, process and visualise your IoT application data. It is quick to get started with, and provides easy-to-use REST APIs to help you decouple your sensor infrastructure and focus on pushing the data out to the platform, where you can transform it to a higher level application domain. It is an excellent platform to build your IoT proof-of-concept application and take your idea to a wider audience. [RTO](#)
