

## Linux Foundation develops EdgeX Foundry to standardise IoT

The Linux Foundation, along with 50 other companies, is all set to standardise the Internet of Things (IoT) with its EdgeX Foundry. The new project unifies the marketplace around a new common open framework and builds an ecosystem of companies with interoperable plug-and-play components.

Security has been a major

issue with all IoT projects. The Linux Foundation-backed EdgeX Foundry aims to secure the experience by standardising the IoT edge computing model. The new move also eases the growing concern across industry that IoT has been fragmented and suffers from slower growth due to the lack of a common framework.

"EdgeX Foundry is aligning market leaders around a common framework, which will drive IoT adoption and enable businesses to focus on developing innovative use cases that impact the bottom line," said Jim Zemlin, executive director, The Linux Foundation.

The EdgeX development is expected to solve the complexity caused by IoT's wide components range by simplifying the creation of IoT edge solutions. Using interoperable plug-and-play components, the framework will ease IoT product or solution creation for developers. The built-in components can run on any hardware or operating system.

The interoperability between connected devices, services and applications will simplify the creation of IoT projects. Moreover, the open source will give a dynamic nature to the projects, letting end customers adapt to changing business needs.

Dell is helping EdgeX Foundry with early stage FUSE source code under Apache 2.0. The FUSE project is a layer builder between messaging protocols used by sensor networks and cloud server layers.

Organisations like Advance Micro Devices, Bayshore Networks, Linaro, Dell, Canonical, VMware and NetFoundry are the founding members of the EdgeX Foundry.

## OpenSUSE Tumbleweed users receive snapshot updates

OpenSUSE has received the latest set of updates and fixes. OpenSUSE Tumbleweed users stand to gain with this move because of the use of advanced technologies like KDE Plasma 5.9.5 and the GNOME 3.24.1 environment.

Douglas DeMaio from the OpenSUSE project announced the new updates. He highlighted the presence of the Thunderbird 52.1.0 email client, the KDE frameworks 5.33.0, the Vim 8.0.566 editor, the Mesa 17.0.4 3D graphics library and the Zypper

1.13.24 package manager, in addition to the fresh environments. These latest updates also include important security fixes for numerous packages in Tumbleweed.

Additionally, the open source community has received the OpenSUSE Leap 42.3 Build 0184 release

## GitHub open sources its DNS records management tool

GitHub has open sourced its tool for managing DNS records. Called OctoDNS, the new development has notable features that make it easier to create redundancy.

DNS systems have become a critical focus for cyber attackers since the last year. Therefore, GitHub has developed OctoDNS and started using its presence internally, ahead of open sourcing the code.

GitHub has leveraged OctoDNS to keep all its records across the various domains in sync with multiple providers. If a DNS provider has an issue, there is an alternate DNS to serve user requests. This gives a reason to the code-sharing platform to use the tool for numerous domains.

“OctoDNS has allowed us to revamp our DNS workflow. Our zones and records are laid out in config files stored in a Git repo,” GitHub’s infrastructure engineer Ross McFarland said in a statement.

The open source availability of OctoDNS allows anyone to submit pull requests to make changes in any of the zones and records. If particular team members know the name that they want, they can directly enter the URL and make the appropriate changes in any particular file. Previously, you were required to make such changes manually.

GitHub's OctoDNS supports commercial providers such as Cloudflare, Dynect, DNSimple, PowerDNS and Route53. You can also manually select sources and providers from the available directories on the GitHub repository.
