

```
$ apt-get install python-networking-odl
```

Now, restart the Neutron server and check its status. It should be running without errors.

Step 7: Verify the integration

We have almost completed the integration of OpenStack with VTN. Now, create initial networks in OpenStack and check whether a new network is created and posted to ODL, for which VTN Manager creates a VTN.

Use the `curl` commands given below to verify the creation of the network and VTN:

```
$ curl --user "admin":"admin" -H "Content-type: application/json" -X GET http://<ODL_IP>:8181/restconf/operational/vtn:vtns/
$ curl -u admin:admin http://<ODL_IP>:8080/controller/nb/v2/neutron/networks
```

Whenever a new sub-network is created in the OpenStack Horizon, VTN Manager will handle it and create a vBridge under the VTN. When you create a new VM in OpenStack, the interface (br-int) mentioned as the integration bridge in the configuration file will be added with more interfaces, and the network is provisioned for it by the VTN Neutron bundle. The addition of the new port is captured by VTN Manager, and it creates a vBridge interface with port mapping.

When the VM starts to communicate with the other

VMs that have been created, VTN Manager will install flows in the OVS and other OpenFlow switches to facilitate communication between the VMs.

Note: To access OpenDaylight RestConf API documentation, use the link http://<ODL_IP>:8181/apidoc/explorer/index.html, which points to your `ODL_IP`.

If everything works correctly, you will be able to communicate with other VMs created in the different compute nodes.

The VTN project doesn't support the vRouter up to the Boron release, which means that the floating IP operation in OpenStack is not supported when integrating VTN Manager with OpenStack. It might support the vRouter in the Carbon or Nitrogen releases.
