Figure 10: Overall key findings

explored in this article:

- Tempest test results across different OpenStack releases and OS flavours are distinct.
- One of the primary reasons for this ambiguity is that each OS flavour has different kernel versions.
- The newer the kernel version used, the more stable are the test results.
- Tempest test results across different OpenStack releases are distinct because different OpenStack releases on different hardware platforms are used.

Continued from Page 36...

```
;extension=php_imap.dll
;extension=php_interbase.dll
;extension=php_ldap.dll
;extension=php_mbstring.dll
;extension=php_exif.dll ; Must be after mbstring as it depends on it
;extension=php_mysql.dll
;extension=php_mysqli.dll
;extension=php_oci8_12c.dll ; Use with Oracle Database 12c Instant Client
;extension=php_openssl.dll
;extension=php_pdo_firebird.dll
;extension=php_pdo_mysql.dll
;extension=php_pdo_oci.dll
;extension=php_pdo_odbc.dll
;extension=php_pdo_sqlite.dll
```

Figure 8: Uncommenting mysql modules

Figure 9: Running Localhost

seen in Figure 9 shows up, we have the confirmation that our servers are running fine because we can see the files inside the *localhost* index. To access the folder, go to the C:\ drive and open the Apache folder. Find a folder named *htdocs* and create a new file named *info.php* inside it. Then type the following:

```
<?PHP
PHPinfo();
?>
```

Again, go to your browser and type *localhost/info.php* in the URL search bar to get information about the PHP version.

To see the list of all the modules that are loaded, I suggest you restart your system. Open your browser, and type *localhost* in the URL search bar.

If something like what's

- Tempest execution on the Liberty release on various Linux OS flavours yields more stable test results as compared to the Kilo release.
- The more recent the OpenStack version, the more stable are the test results. [END](#)
